(54) Title: AZA-BENZAZOLIUM CONTAINING CYANINE DYES

(57) Abstract

Unsymmetrical cyanine dyes that incorporate an aza-benzazolum ring moiety are described, including cyanine dyes substituted by a cationic side chain, monomeric and dimeric cyanine dyes, chemically reactive cyanine dyes, and conjugates of cyanine dyes. The subject dyes are virtually non-fluorescent when diluted in aqueous solution, but exhibit bright fluorescence when associated with nucleic acid polymers such as DNA or RNA, or when associated with detergent-complexed proteins. A variety of applications are described for detection and quantitation of nucleic acids and detergent-complexed proteins in a variety of samples, including solutions, electrophoretic gels, cells, and microorganisms.

AZA-BENZAZOLIUM CONTAINING CYANINE DYES

FIELD OF THE INVENTION

5 The invention relates to cyanine dyes that possess particular utility as fluorescent stains for nucleic acids and poly(amino acids). In particular, the invention relates to materials that are unsymmetrical cyanine dyes incorporating an aza-benzazolum moiety. The subject dyes, which form fluorescent complexes in combination with nucleic acids or lipid-complexed poly(amino acids), can be used in analyzing a wide range of materials, including biological and environmental samples.

BACKGROUND INFORMATION

10 Unsymmetrical cyanine dyes have previously been used as fluorescent stains for nucleic acids, see for example U.S. Patent No. 4,883,867 to Lee, et al. (1989); U.S. Patent No. 4,937,198 to Lee, et al. (1990); U.S. Patent No. 5,321,130 to Yue et al. (1994); U.S. Patent No. 5,410,030 to Yue et al. (1995); U.S. Patent No. 5,436,134 to Haugland et al. (1995); U.S. Patent No. 5,582,977 to Yue et al. (1996); U.S. Patent No. 5,658,751 to Yue et al. (1997); and U.S. Patent No. 5,863,753 to Haugland et al. (1999).

20 The general spectral properties of the previously described cyanine dyes could be selected somewhat by changing the number of methine groups in the dye, and whether the dye incorporated a pyridinium or quinolinium ring system. The spectral properties of cyanine dyes can be more finely adjusted by selection of appropriate dye substituents. However, there were nevertheless regions of the visible spectrum where suitable fluorescent cyanine dyes either did not exist, or did not possess particularly favorable fluorescence properties.

25 The dyes of the invention incorporate additional nitrogen atoms in the aromatic benzazolum portion of the dye. The dyes of the invention exhibit a bathochromic spectral shift (a shift to longer wavelength) of approximately 30 to 50 nm relative to otherwise structurally similar cyanine dyes known in the art. This bathochromic spectral shift yields dyes that are particularly useful for excitation in the wavelength ranges between 500 nm and 600 nm and at >630 nm. Of particular importance are the dyes of the invention that exhibit absorbance maxima between 530 nm and 550 nm, as they match the principal emission lines of the mercury arc lamp (546 nm), frequency-doubled Nd-Yag laser (532 nm), and HeNe laser (543 nm).

30 Styryl dyes that complex with lipid-complexed poly(amino acids) have been described previously (U.S. Patent No. 5,616,502 to Haugland et al., 1997)). Cyanine dyes that incorporate a 3,4-diazaindene ring system have been described previously for use as optical sensitizers in photographic materials (British patent No. 870,753 to Ficken et al., (1961)), but their use in association with either nucleic acids or lipid-complexed proteins as fluorescent stains has not previously been described.

SUMMARY OF THE INVENTION AND DESCRIPTION OF THE PREFERRED EMBODIMENTS

The invention comprises unsymmetrical cyanine dyes that incorporate an aza-benzazolium ring moiety. Included in the invention are monomeric and dimeric cyanine dyes, including those substituted by a cationic side chain, a chemically reactive functional group, and a conjugated substance. The dyes of the invention are virtually non-fluorescent when diluted in aqueous solution. When associated with nucleic acid polymers such as DNA or RNA, however, the resultant dye-nucleic acid complex is extremely fluorescent upon illumination. Similarly, when associated with lipid-complexed poly(amino acids), the resulting composition is extremely fluorescent upon illumination. The dyes of the present invention stain nucleic acids in a wide variety of samples, particularly in aqueous solutions, electrophoretic gels, and a wide variety of cells, including microorganisms. The dyes of the present invention stain poly(amino acids) in a wide variety of samples, particularly in electrophoretic gels.

The dyes of the invention comprise a cyanine dye that contains: 1) a first heterocyclic ring system that is a substituted aza-benzazolium ring, 2) a bridging methine and 3) a second heterocyclic ring system that is a pyridine, a quinoline, a pyridinium or a quinolinium. In one embodiment of the invention, the first or second ring system is substituted by a side chain, TAIL, that contains at least one heteroatom. In another embodiment, the first or second ring system is covalently bound to a second cyanine dye, forming a homo- or heterodimer. The first and second ring systems of the first or second cyanine dye is optionally further substituted by a variety of substituents, including chemically reactive groups as described below.

Pyridinium and quinolinium-based monomeric dyes

In one embodiment, the dyes of the invention have the formula

wherein A represents the atoms necessary to form one or more fused 6-membered aromatic rings,
 5 incorporating at least one nitrogen atom =N(R²)_β-. The six membered rings of the aza-benzazole ring system typically incorporate 1-3 nitrogen atoms, more preferably 1-2 nitrogen atoms, typically incorporated in the first 6-membered aromatic ring fused to the azole ring. Preferred embodiments of the aza-benzazole moiety include without limitation the following structures,

At least one of the aza-benzazole nitrogen atoms is quaternized by the substituent R²,
 15 resulting in a formal positive charge. In one embodiment, α = 1 and β = 0, such that the azole nitrogen atom is quaternized, and the benzo nitrogen atom is unsubstituted. In another embodiment, α = 0 and β = 1, such that the azole nitrogen atom is unsubstituted and at least one benzo nitrogen atom is quaternized by R². Either α or a β is 1, and typically no more than one β in a given aza-benzazole is 1. The presence of an additional nitrogen atom incorporated in the fused
 20 aromatic ring of the benzazole moiety results in a shift of the emission spectra to longer wavelength. The presence of additional nitrogen atoms (as in structure IV, above) shift the wavelength even further, as does the presence of additional fused 6-membered rings.

The aza-benzazole moiety is optionally further substituted at one or more aromatic carbons by alkyl having from 1-6 carbons, alkoxy having from 1-6 carbons, trifluoromethyl, or halogen. Although the carbon atoms of the aza-benzazolium ring system are typically fully substituted by hydrogen, incorporation of one or more non-hydrogen substituents can be used to fine tune the absorption and emission spectrum of the resulting dye. Typically, where present, there is only one non-hydrogen substituent on the aza-benzazole, preferably an alkoxy or halogen substituent.

The substituent R² is an alkyl group having 1-22 carbons, that is linear or branched, saturated or unsaturated, that is optionally substituted one or more times by hydroxy, carboxy, sulfo, amino, amino substituted by 1-2 C₁-C₆ alkyls, or ammonium substituted by 1-3 C₁-C₆ alkyls.

The R² substituent is alternatively a TAIL moiety, as described below. In one embodiment particularly suited for staining nucleic acids, R² is alkyl having 1-6 carbons, preferably methyl or ethyl, more preferably methyl. In another embodiment particularly suitable for staining lipid-complexed poly(amino acids), R² is a sulfoalkyl having 2-6 carbons.

In one embodiment, X is one of O, S, Se or NR¹⁵, where R¹⁵ is H or an alkyl group having 1-22 carbons, that is linear or branched, saturated or unsaturated, that is optionally substituted one or more times by hydroxy, carboxy, sulfo, amino, amino substituted by 1-2 C₁-C₆ alkyls, or ammonium substituted by 1-3 C₁-C₆ alkyls. The R¹⁵ substituent is alternatively a TAIL moiety.

Alternatively, X is CR¹⁶R¹⁷, where R¹⁶ and R¹⁷, which may be the same or different, are independently H or alkyl groups having 1-22 carbons, that are linear or branched, saturated or unsaturated, that are optionally substituted one or more times by hydroxy, carboxy, sulfo, amino, amino substituted by 1-2 C₁-C₆ alkyls, or ammonium substituted by 1-3 C₁-C₆ alkyls. Alternatively, one of R¹⁶ and R¹⁷ is a TAIL moiety. Alternatively, the carbons of R¹⁶ and R¹⁷ taken in combination complete a five or six membered saturated ring. When X is CR¹⁶R¹⁷, R¹⁶ and R¹⁷ are typically alkyls having 1-6 carbons, preferably methyl or ethyl.

Preferably, X is O or S, more preferably X is S.

The two heterocyclic ring systems of the cyanine dye are linked by a bridging methine having the formula

(where n = 0, 1, or 2) in such a way as to permit extensive electronic delocalization. When n = 0 the dyes are unsymmetrical monomethine dyes; when n = 1 the dyes are trimethine dyes; when n = 2, the dyes are pentamethine dyes. As with similar compounds, the number of methine groups between the heteroaromatic rings influences the spectral properties of the dye. The monomethine dyes of the present invention typically have yellow to orange to red fluorescence emission. The trimethine dye analogs are substantially shifted toward red wavelengths beyond 600 nm, and the pentamethine dyes are shifted even further, often exhibiting infrared fluorescence emission. Preferably n = 0 or 1,

Methine substituents R^{30} , R^{31} , and R^{32} are independently H, alkyl having 1-6 carbons, cycloalkyl having 3-10 carbons, aryl, or heteroaryl. Where $n = 1$ or 2, each R^{31} and R^{32} varies independently. In one embodiment, only the substituent on the central carbon of the methine bridge is nonhydrogen (R^{30} where $n = 0$, R^{31} where $n = 1$, the centrally located R^{32} where $n = 2$). In another embodiment, where a methine substituent is nonhydrogen it is an alkyl. In another embodiment, where a methine substituent is nonhydrogen it is an aryl. Typically, each R^{30} , R^{31} , and R^{32} is hydrogen. Where R^{30} , R^{31} , or R^{32} is nonhydrogen, preferably $n = 1$.

In one aspect of the invention, selected cyanine dyes having nonhydrogen methine substituents have particular utility as RNA selective nucleic acid stains. In another aspect of the invention, cyanine dyes having nonhydrogen methine substituents increase the signal-to-noise ratio when staining nucleic acids by decreasing background fluorescence.

The incorporation of substituted methine bridges, as described above, also provides useful derivatives of previously described cyanine dyes (e.g., U.S. Patent No. 5,321,130 to Yue et al. (1994); U.S. Patent No. 5,410,030 to Yue et al. (1995); U.S. Patent No. 5,436,134 to Haugland et al. (1995); U.S. Patent No. 5,582,977 to Yue et al. (1996); U.S. Patent No. 5,658,751 to Yue et al. (1997); and U.S. Patent No. 5,863,753 to Haugland et al. (1999)).

The second ring system contains a ring fragment Y that is $-CR^3=CR^4-$, with subscripts p and m equal to 0 or 1, such that $p + m = 1$. The second ring system is a 6 membered heterocycle according to one of these formulations

or

In preferred embodiments of the invention, $m = 1$ and $p = 0$ ("4-pyridiniums" and "4-quinoliniums").

The pyridinium and quinolinium-based cyanine dyes include an N-substituent R^5 that is an alkyl that is saturated or unsaturated, linear or branched, having 1-22 carbons, that is optionally substituted one or more times by hydroxy, carboxy, sulfo, amino, amino substituted by 1-2 C_1-C_6 alkyls, or ammonium substituted by 1-3 C_1-C_6 alkyls. Alternatively, R^5 is a CYCLIC

SUBSTITUENT or a TAIL moiety, as described below. Typically R^5 is an alkyl having 1-6 carbons, preferably 1-2 carbons, or R^5 is a CYCLIC SUBSTITUENT. In one embodiment, R^5 is a sulfoalkyl having 2-6 carbons. In another embodiment, R^5 is a pair of electrons, resulting in a neutral unsymmetrical cyanine dye, as described below.

5 The substituents of the second ring system, R^3 , R^4 , R^6 , and R^7 , are independently H, halogen, an alkyl that is saturated or unsaturated, linear or branched, having 1-6 carbons, or a CYCLIC SUBSTITUENT as described below, or a TAIL moiety, as described below. R^3 , R^4 , R^6 , and R^7 are optionally $-OR^8$, $-SR^8$, or $-(NR^8R^9)$ where R^8 and R^9 , which can be the same or different, are independently alkyl groups having 1-6 carbons; or 1-2 alicyclic or aromatic rings; or R^8 and R^9 taken
10 in combination form a cyclic structure having the formula $-(CH_2)_2-W-(CH_2)_2-$, where W is a single bond, $-O-$, $-CH_2-$, or $-NR^{10}-$, where R^{10} is H or an alkyl having 1-6 carbons. In addition, R^3 , R^4 are optionally and independently $-OSO_2R^{19}$ where R^{19} is alkyl having 1-6 carbons, or perfluoroalkyl having 1-6 carbons, or aryl.

Optionally, R^6 and R^7 taken in combination are $-(CH_2)_v-$ where $v = 3$ or 4 , forming a fused 5-
15 or 6-membered ring, or R^6 and R^7 , taken in combination form a fused 6-membered aromatic ring.

Alternatively, any of R^3 , R^4 , R^6 or R^7 is a CYCLIC SUBSTITUENT, as defined below. Preferred ring substituents are independently H, alkyl, $-OR^8$, or a CYCLIC SUBSTITUENT, or a TAIL. In one aspect of the invention, R^4 is not hydrogen. In another aspect of the invention, R^4 is a CYCLIC SUBSTITUENT, a TAIL moiety, or a CYCLIC SUBSTITUENT that is further substituted
20 by a TAIL moiety.

Where R^6 and R^7 taken in combination form a fused 6-membered aromatic ring, embodiments of this invention are quinolinium derivatives, and the second ring system has the formula

25 where ring substituents R^{11} , R^{12} , R^{13} , and R^{14} are independently H, an alkyl that is saturated or unsaturated, linear or branched, having 1-6 carbons; halogen; or $-OR^8$, $-SR^8$, $-(NR^8R^9)$, where R^8 and R^9 are as defined previously; or a CYCLIC SUBSTITUENT, as defined below, or a TAIL moiety, as defined below. Typically no more than one of R^{11} , R^{12} , R^{13} , and R^{14} is nonhydrogen, and is preferably halogen or $-OR^8$. Preferred embodiments of the invention are quinoliniums wherein $m = 1$ and $p = 0$
30 ("4-quinoliniums"). The presence of the fused 6-membered ring at R^6 and R^7 typically increases the wavelength of the dye's fluorescence when associated with nucleic acids or lipid-complexed poly(amino acids).

Where the dye is substituted by a TAIL moiety, typically one or more of R^2 , R^3 , R^4 , R^5 , R^6 , R^7 ,

R¹¹, R¹², R¹³ and R¹⁴ is a TAIL. In one embodiment of the invention, at least one of R³, R⁴, R⁵, R⁶, R⁷, R¹¹, R¹², R¹³ and R¹⁴ is required to be a TAIL. Where the dye is substituted by a CYCLIC SUBSTITUENT, typically one of R³, R⁴, R⁵, R⁶, R⁷, R¹¹, R¹², R¹³ and R¹⁴ is a CYCLIC SUBSTITUENT. Preferably, one or more of R⁴, R⁵, R⁶, or R¹² is TAIL or a CYCLIC SUBSTITUENT, including CYCLIC SUBSTITUENTS that are substituted by TAIL moieties. More preferably, R⁴ or R⁵ is a TAIL or a TAIL-substituted CYCLIC SUBSTITUENT. When R⁴ is a TAIL, LINK is preferably -NR²⁰- or -S-. When TAIL is at any position other than R⁴ or R⁵, LINK is preferably -O- or a single bond.

In a specific embodiment of the invention, the dyes of the invention are 4-pyridiniums or 4-quinoliniums, wherein R⁵ is an alkyl having 1-6 carbons, or R⁵ is a CYCLIC SUBSTITUENT, and R⁴ is not hydrogen. Dyes having an R⁴ substituent that is non-hydrogen typically possess enhanced quantum yields relative to similar dyes wherein R⁴ is H. For this class of dyes, R⁵ is preferably alkyl having 1-6 carbons. Preferably R⁴ is a TAIL.

In an additional preferred embodiment of the invention, the second heterocyclic ring contains exactly two non-hydrogen substituents, one of which is a TAIL.

Some of the dyes of the present invention that possess a TAIL moiety at R⁴ or R⁵ exhibit particular utility for staining nucleic acids in cells and microorganisms. The utility of specific embodiments of the dyes of the present invention in staining cells and microorganisms is generally dependent on the chemical nature of the TAIL moiety, and the identity of the group present at R⁵. For example, those compounds for which CAP is a quaternary ammonium salt are generally impermeant to living cells, with the exception of some yeast cells. However, the permeability of those compounds for which CAP is a primary or secondary amine, and LINK is a secondary or tertiary amine, is typically related to the nature of R⁵ (the N-substituent).

Typically, dyes useful as impermeant cellular probes are those dyes having 2 or more positive charges overall, more preferably 3 or more positive charges. Preferred dyes for permeant cellular probes are dyes wherein R⁵ is aryl or heteroaryl and CAP is -O-R²¹ or -S-R²¹, or dyes wherein R⁴ is a CYCLIC SUBSTITUENT substituted by a cationic TAIL (for example, Compound 24, Example 10).

Dyes that are preferred for staining nucleic acids present in electrophoretic gels typically have a CAP that is a dialkylamino group, while dyes useful as stains for poly(amino acids) in electrophoretic gels are overall neutral in charge, typically by virtue of a sulfoalkyl group present at R² or R⁵ that balances the cationic charge on the aza-benzazole moiety.

Any net positive or negative charges possessed by the dyes of the invention are balanced by a necessary counterion or counterions. Typically, the dyes of the invention are positively charged due to the presence of a quaternized aza-benzazole nitrogen, however the overall charge on the dye is determined by the charge present on each dye substituent (such as a negatively charged sulfonic acid group, or a positively charged ammonium group). Where necessary, the counterion is depicted as Ψ and the polarity of the charge is indicated. Examples of useful counterions for dyes having a net positive charge include, but are not limited to, chloride, bromide, iodide, sulfate, alkanesulfonate,

arylsulfonate, phosphate, perchlorate, tetrafluoroborate, tetraarylboride, nitrate and anions of aromatic or aliphatic carboxylic acids. Preferred negative counterions are chloride, iodide, perchlorate and various sulfonates. Examples of useful counterions for dyes having a net negative charge include, but are not limited to, alkali metal ions, alkaline earth metal ions, transition metal ions, ammonium or substituted ammonium ions. Preferably, any necessary counterion is biologically compatible, is not toxic as used, and does not have a substantially deleterious effect on biomolecules.

CYCLIC SUBSTITUENT

As used herein, a CYCLIC SUBSTITUENT is a substituted or unsubstituted aryl, heteroaryl, or cycloalkyl having 3-10 carbons. As used herein, an aryl is a phenyl or a naphthyl group, and a heteroaryl substituent is a 5 or 6-membered heteroaromatic ring, wherein the heteroatom is O, N or S. The CYCLIC SUBSTITUENT is optionally substituted by halogen, amino, alkyl, perfluoroalkyl, alkylamino, dialkylamino, alkoxy or carboxyalkyl, wherein each alkyl group has 1-6 carbons, or by a TAIL moiety. The CYCLIC SUBSTITUENT is preferably a substituted or unsubstituted naphthyl, phenyl, thienyl, or cycloalkyl having 3-10 carbons, more preferably, the CYCLIC SUBSTITUENT is phenyl.

Cyanine dyes incorporating at least one TAIL moiety

In one embodiment, the cyanine dyes of the invention are substituted by at least one TAIL moiety. TAIL is a heteroatom-containing side chain, that is described by the formula LINK-SPACER-CAP. LINK is the linking moiety by which TAIL is attached to the dyes of the present invention. SPACER is a covalent linkage that connects LINK to CAP. CAP is the portion of TAIL that possesses a heteroatom component.

LINK is a single covalent bond, an ether linkage (-O-), a thioether linkage (-S-), or an amine linkage (-NR²⁰-). In each embodiment, LINK forms the attachment between the cyanine dye core structure and SPACER. When LINK is an amine, the amine substituent (R²⁰) is optionally H, such that LINK = -NH-. Alternatively, R²⁰ is a linear or branched alkyl having 1-8 carbons. In another embodiment of the invention, R²⁰ is -SPACER'-CAP', yielding a TAIL having the formula

where SPACER' and CAP', respectively, may be the same as or different from SPACER and CAP, and are selected from the same alternatives defined for SPACER and CAP, respectively. For the sake of simplifying the description, SPACER and CAP are defined with the understanding that a

description of SPACER includes SPACER', and a description of CAP includes CAP'.

SPACER is a covalent linkage that joins LINK and CAP. SPACER is a linear, branched, cyclic, heterocyclic, saturated or unsaturated arrangement of 1-16 C, N, P, O or S atoms.

Alternatively, SPACER is a single covalent bond, such that both LINK and SPACER are not
5 simultaneously single covalent bonds. Preferably, the SPACER linkage must begin and end with a carbon atom. Typically, if SPACER consists of a single atom, it is required to be a carbon atom, so that the first and last atom in SPACER (in this specific instance, they are the same atom) is a carbon. The 1-16 atoms making up SPACER are combined using any appropriate combination of
10 ether, thioether, amine, ester, or amide bonds; or single, double, triple or aromatic carbon-carbon bonds; or phosphorus-oxygen bonds; or phosphorus-sulfur bonds; or nitrogen-nitrogen bonds; or nitrogen-oxygen bonds; or aromatic or heteroaromatic bonds. SPACER is further substituted by hydrogen to accommodate the valence state of each atom in SPACER.

Generally, the atoms of SPACER are arranged such that all heteroatoms in the linear backbone of SPACER are separated by at least one carbon atom, and preferably separated by at least
15 two carbon atoms. Typically, SPACER is 1-6 carbon atoms in a linear or branched saturated chain. In one embodiment of the invention, SPACER incorporates a 6-membered aromatic ring (phenylene linkage). In another embodiment of the invention, SPACER incorporates a 5- or 6-membered heteroaromatic ring, wherein the heteroatoms are O, N, or S. Alternatively, SPACER incorporates amide linkages, ester linkages, simple ethers and thioethers, and amines in a linear arrangement,
20 such as $-\text{CH}_2-\text{CH}_2-(\text{C}=\text{O})-\text{NH}-\text{CH}_2-\text{CH}_2-\text{CH}_2-$. Preferably, SPACER is an alkylene $(-\text{CH}_2)_k$, where $k = 1-8$).

LINK and SPACER, in combination, serve to attach a heteroatom-containing group, CAP, to the dye core structure. CAP may contain oxygen, sulfur or nitrogen, according to the formulas $-\text{O}-\text{R}^{21}$, $-\text{S}-\text{R}^{21}$, $-\text{NR}^{21}\text{R}^{22}$, or $-\text{NR}^{21}\text{R}^{22}\text{R}^{23}$. The substituents R^{21} , R^{22} , and R^{23} are independently H, or a
25 linear or branched alkyl or cycloalkyl having 1-8 carbons. Where any of R^{21} , R^{22} and R^{23} are alkyl or cycloalkyl, they are optionally further substituted by one or more halogen, hydroxy, alkoxy having 1-8 carbons, amino, carboxy, sulfo, or phenyl, where phenyl is optionally further substituted by halogen, hydroxy, alkoxy having 1-8 carbons, amino, aminoalkyl having 1-8 carbons, or sulfoalkyl or carboxyalkyl having 1-8 carbons. In another embodiment of the invention, one or more of R^{21} , R^{22}
30 and R^{23} , taken in combination with R^{20} and SPACER, or with SPACER alone, forms a 5- or 6-membered ring that is aromatic, heteroaromatic, alicyclic or heteroalicyclic ring. When the 5- or 6-membered ring is heteroaromatic or heteroalicyclic, the ring contains 1-3 heteroatoms that are O, N or S. Preferably, R^{21} and R^{22} are independently hydrogen or alkyls having 1-8 carbons. R^{23} is typically H or alkyl having 1-8 carbons.

35 When CAP is $-\text{NR}^{21}\text{R}^{22}\text{R}^{23}$, the CAP nitrogen atom is formally positively charged., and adds to the cumulative charge that is balanced by the presence of the counterion Ψ^- .

Additionally, there are several embodiments of the present invention wherein CAP incorporates a cyclic structure. In these embodiments, CAP typically incorporates a 5- or 6-

membered nitrogen-containing ring, optionally including an additional heteroatom (typically oxygen), where the ring nitrogen is optionally substituted by R^{23} to give an ammonium salt. Specific versions of CAP include, but are not limited to, those listed in Table 1.

5 Table 1: Examples of specific CAP moieties

				
				

CAP is preferably $-NR^{21}R^{22}$ or $-NR^{21}R^{22}R^{23}$, where R^{21} , R^{22} , and R^{23} are alkyls having 1-6 carbons. More preferably CAP is $-N(CH_3)_2$ or $-N(CH_3)_3$.

Preferably TAIL contains 6-10 non-hydrogen atoms, including LINK and CAP.

10 Selected examples of TAIL are listed in Table 2. For each TAIL, the identities of LINK, SPACER and CAP are specified. Where R^{21} , R^{22} , or R^{23} combined with either R^{20} or SPACER, the combination is indicated in the table.

Table 2: Specific examples of TAIL moieties

TAIL	LINK	SPACER	CAP
		SPACER'	CAP'
		$-CH_2-CH_2-CH_2-$	$-N(CH_3)_2$

		-CH ₂ -CH ₂ -CH ₂ -	-N(CH ₃) ₃
		-CH ₂ -CH ₂ -CH ₂ -	-N(CH ₃) ₂
		-CH ₂ -CH ₂ -CH ₂ -	-N(CH ₃) ₂

In another embodiment of the invention, the cyanine dyes of the invention are described by the formula

5

where A, X, R², α, β, n, Y_m, Y_p, R³, R⁴, R⁵, R⁶, R⁷, R⁸, R⁹, R¹⁰, R¹¹, R¹², R¹³, R¹⁴, R¹⁵, R¹⁶, R¹⁷, R¹⁸, R¹⁹, R²⁰, R²¹, R²², R²³, R²⁴, R³⁰, R³¹, R³², TAIL, CYCLIC SUBSTITUENT, and substitution patterns and preferences are as defined previously. These 'free base' versions of the cyanine dyes of the invention are not derivatized by an R⁵ substituent, and incorporate an aza-benzazole ring system, a methine moiety, and a pyridine or quinoline ring system. Related neutral cyanine dyes are described in U.S. Patent 5,656,449 to Yue (1997).

15 Dimers of unsymmetrical cyanine dyes

In another embodiment of the invention, the dye of the invention is a homodimer or heterodimer of unsymmetrical cyanine dyes. That is, two cyanine dye subunits, at least one of which has a structure as described above, are joined by a covalent linkage, BRIDGE, to yield a dimeric compound having utility as a fluorescent stain for nucleic acids or lipid-complexed poly(amino acids) (see Compound 28, Example 12 and Compound 46, Example 13). While one cyanine dye subunit is an aza-benzazolium based cyanine dye subunit, the other portion of the dimeric dye may be a cyanine dye as described previously by Haugland and Yue (U.S. Patent No. 5,321,130; U.S. Patent No. 5,436,134; U.S. Patent No. 5,658,751; and U.S. Patent No. 5,869,689). Alternatively, the other portion of the dimeric dye is dissimilar in structure, for example a phenanthridium moiety.

The BRIDGE moiety is typically a combination of atoms having stable chemical bonds. The BRIDGE moiety optionally includes single, double, triple or aromatic carbon-carbon bonds, as well as carbon-nitrogen bonds, nitrogen-nitrogen bonds, carbon-oxygen bonds and carbon-sulfur bonds. The BRIDGE moiety typically includes ether, thioether, carboxamide, sulfonamide, urea, urethane or hydrazine moieties. Preferred BRIDGE moieties have 1-20 nonhydrogen atoms selected from the group consisting of C, N, O and S; and are composed of any combination of ether, thioether, amine, ester, carboxamide, sulfonamide, hydrazide bonds and aromatic or heteroaromatic bonds. Preferably BRIDGE is a combination of single carbon-carbon bonds and carboxamide or thioether

bonds. Examples of BRIDGE include substituted or unsubstituted polymethylene, arylene, alkylarylene or arylenealkyl.

In a preferred embodiment, the BRIDGE moiety is an aliphatic chain containing a backbone of 4-19 carbon atoms. The carbon backbone may be interspersed at one or more intervals with a non-carbon heteroatom. The heteroatoms, which may be the same or different are N, O, or S, preferably N. Where the heteroatom is nitrogen, it is optionally substituted with one or more alkyl substituents having 1-6 carbon atoms, which may be the same or different. BRIDGE moieties that incorporate quaternary nitrogens confer cationic charges on the dimers of the invention, potentially increasing their affinity for nucleic acids, as well as decreasing their ability to permeate cell membranes.

Where the dimeric dye incorporates two cyanine subunits, the BRIDGE moiety is independently bound to each cyanine subunit at one of R², R³, R⁴, R⁵, R⁶, R⁷, R¹¹, R¹², R¹³, or R¹⁴, as defined above. Preferably the BRIDGE moiety is independently bound to each cyanine subunit at R², R⁴ or R⁵, more preferably at R⁴ or R⁵.

By careful selection of the cyanine subunits that are covalently joined to form the dimeric dye, a variety of dimers with desirable spectral properties may be prepared. Selection of subunits that function as an energy donor and energy acceptor, respectively, via fluorescence resonance energy transfer typically produces a dimeric stain with an enhanced Stokes shift. The necessary difference in spectral properties for energy transfer to occur may be created by covalently attaching an aza-benzothiazole cyanine subunit to an aza-benzoxazole cyanine subunit. Alternatively, a monomethine cyanine subunit may be attached to a trimethine or pentamethine cyanine subunit, or a cationic cyanine subunit may be attached to a neutral cyanine dye subunit. In another aspect of the invention, an aza-benzoxazole cyanine subunit is attached to a non aza-substituted cyanine subunit. In yet another aspect of the invention, an aza-benzoxazole cyanine subunit is attached to a non-cyanine subunit, typically a phenanthridium subunit. Dimeric dyes incorporating non-aza-benzazolum containing cyanine subunits have previously been described (U.S. Patent No. 5,582,977 to Yue et al. (1996); U.S. Patent No. 5,401,847 to Glazer, (1995); U.S. Patent No. 5,565,554 to Glazer (1996); and U.S. 5,760,201 to Glazer et. al. (1998)).

Reactive cyanine dyes and dye-conjugates

In another embodiment of the invention, the cyanine dyes of the invention are chemically reactive, and are substituted by at least one group -L-R_x, where R_x is the reactive group that is attached to the dye by a covalent linkage L. In certain embodiments R_x is attached to the dye by multiple intervening atoms that serve as a spacer. The reactive dyes label a wide variety of organic or inorganic substances that contain or are modified to contain functional groups with suitable reactivity, resulting in chemical attachment of the conjugated substance (S_c), represented by -L-S_c. This conjugation typically confers the nucleic acid- and/or poly(amino acid)-sensing abilities of the cyanine dye on the conjugated substance. The reactive group and functional group are typically an

electrophile and a nucleophile that can generate a covalent linkage. Alternatively, the reactive group is a photoactivatable group, and becomes chemically reactive only after illumination with light of an appropriate wavelength. Selected examples of functional groups and linkages are shown in Table 3, where the reaction of an electrophilic group and a nucleophilic group yields a covalent linkage.

5

Table 3: Examples of some routes to useful covalent linkages

Electrophilic Group	Nucleophilic Group	Resulting Covalent Linkage
activated esters*	amines/anilines	carboxamides
acyl azides**	amines/anilines	carboxamides
acyl halides	amines/anilines	carboxamides
acyl halides	alcohols/phenols	esters
acyl nitriles	alcohols/phenols	esters
acyl nitriles	amines/anilines	carboxamides
aldehydes	amines/anilines	imines
aldehydes or ketones	hydrazines	hydrazones
aldehydes or ketones	hydroxylamines	oximes
alkyl halides	amines/anilines	alkyl amines
alkyl halides	carboxylic acids	esters
alkyl halides	thiols	thioethers
alkyl halides	alcohols/phenols	ethers
alkyl sulfonates	thiols	thioethers
alkyl sulfonates	carboxylic acids	esters
alkyl sulfonates	alcohols/phenols	ethers
anhydrides	alcohols/phenols	esters
anhydrides	amines/anilines	carboxamides
aryl halides	thiols	thiophenols
aryl halides	amines	aryl amines
aziridines	thiols	thioethers
boronates	glycols	boronate esters
carboxylic acids	amines/anilines	carboxamides
carboxylic acids	alcohols	esters
carboxylic acids	hydrazines	hydrazides
carbodiimides	carboxylic acids	N-acylureas or anhydrides
diazoalkanes	carboxylic acids	esters
epoxides	thiols	thioethers
haloacetamides	thiols	thioethers

halotriazines	amines/anilines	aminotriazines
halotriazines	alcohols/phenols	triazinyl ethers
imido esters	amines/anilines	amidines
isocyanates	amines/anilines	ureas
isocyanates	alcohols/phenols	urethanes
isothiocyanates	amines/anilines	thioureas
maleimides	thiols	thioethers
phosphoramidites	alcohols	phosphite esters
silyl halides	alcohols	silyl ethers
sulfonate esters	amines/anilines	alkyl amines
sulfonate esters	thiols	thioethers
sulfonate esters	carboxylic acids	esters
sulfonate esters	alcohols	ethers
sulfonyl halides	amines/anilines	sulfonamides
sulfonyl halides	phenols/alcohols	sulfonate esters

* Activated esters, as understood in the art, generally have the formula $-CO\Omega$, where Ω is a good leaving group (e.g. oxysuccinimidyl $(-OC_4H_4O_2)$ oxysulfosuccinimidyl $(-OC_4H_3O_2-SO_3H)$, -1-oxybenzotriazolyl $(-OC_6H_4N_3)$; or an aryloxy group or aryloxy substituted one or more times by electron withdrawing substituents such as nitro, fluoro, chloro, cyano, or trifluoromethyl, or combinations thereof, used to form activated aryl esters; or a carboxylic acid activated by a carbodiimide to form an anhydride or mixed anhydride $-OCOR^a$ or $-OCNR^a-NHR^b$, where R^a and R^b , which may be the same or different, are C_1-C_6 alkyl, C_1-C_6 perfluoroalkyl, or C_1-C_6 alkoxy; or cyclohexyl, 3-dimethylaminopropyl, or N-morpholinoethyl).

** Acyl azides can also rearrange to isocyanates

The covalent linkage L binds the reactive group R_x or conjugated substance S_c to the dye, either directly (L is a single bond) or with a combination of stable chemical bonds, optionally including single, double, triple or aromatic carbon-carbon bonds, as well as carbon-nitrogen bonds, nitrogen-nitrogen bonds, carbon-oxygen bonds and carbon-sulfur bonds. L typically includes ether, thioether, carboxamide, sulfonamide, urea, urethane or hydrazine moieties. Preferred L moieties have 1-20 nonhydrogen atoms selected from the group consisting of C, N, O and S; and are composed of any combination of ether, thioether, amine, ester, carboxamide, sulfonamide, hydrazide bonds and aromatic or heteroaromatic bonds. Preferably L is a combination of single carbon-carbon bonds and carboxamide or thioether bonds. The longest linear segment of the linkage L preferably contains 4-10 nonhydrogen atoms including one or two heteroatoms. Examples of L include substituted or unsubstituted polymethylene, arylene, alkylarylene or arylenealkyl. In one embodiment, L contains 1-6 carbon atoms; in another, L is a thioether linkage. In yet another embodiment, L has the formula $-(CH_2)_a(CONH(CH_2)_b)_z$, where a is an integer from 0-5, b is an integer from 1-5 and z is 0 or 1.

The group R_x is bound to the dye via the linker L at R^2 , R^3 , R^4 , R^5 , R^6 , R^7 , R^{11} , R^{12} , R^{13} , or R^{14} . Alternatively, the $-L-R_x$ moiety is bound to one of the aromatic carbons of the aza-benzazole ring

system. Typically, $-L-R_x$ is bound to the dye at R^2 , R^4 or R^5 . Preferably $-L-R_x$ is bound to the dye at R^4 or R^5 .

The selection of covalent linkage to attach the dye to the conjugated substance typically depends on the functional group on the substance to be conjugated. The types of functional groups typically present on the organic or inorganic substances include, but are not limited to, amines, thiols, alcohols, phenols, aldehydes, ketones, phosphates, imidazoles, hydrazines, hydroxylamines, disubstituted amines, halides, epoxides, sulfonate esters, purines, pyrimidines, carboxylic acids, or a combination of these groups. A single type of reactive site may be available on the substance (typical for polysaccharides), or a variety of sites may occur (e.g. amines, thiols, alcohols, phenols), as is typical for proteins. A conjugated substance may be conjugated to more than one dye, which may be the same or different, or to a substance that is additionally modified by a hapten. Although some selectivity can be obtained by careful control of the reaction conditions, selectivity of labeling is best obtained by selection of an appropriate reactive dye.

Typically, R_x will react with an amine, a thiol or an alcohol. In one embodiment, R_x is an acrylamide, an activated ester of a carboxylic acid, an acyl azide, an acyl nitrile, an aldehyde, an alkyl halide, an amine, an anhydride, an aniline, an aryl halide, an azide, an aziridine, a boronate, a carboxylic acid, a diazoalkane, a haloacetamide, a halotriazine, a hydrazine, an imido ester, an isocyanate, an isothiocyanate, a maleimide, a phosphoramidite, a sulfonyl halide, or a thiol group. Preferably, R_x is a carboxylic acid, a succinimidyl ester, an amine, a haloacetamide, an alkyl halide, a sulfonyl halide, an isothiocyanate, a maleimide group, a perfluorobenzamido group, or an azidoperfluorobenzamido group.

A variety of dye-conjugates may be prepared using the reactive dyes of the invention, including conjugates of antigens, steroids, vitamins, drugs, haptens, metabolites, toxins, environmental pollutants, amino acids, peptides, proteins, nucleic acids, nucleic acid polymers, carbohydrates, lipids, and polymers. In another embodiment, the conjugated substance is an amino acid, peptide, protein, polysaccharide, nucleotide, oligonucleotide, nucleic acid, hapten, drug, lipid, phospholipid, lipoprotein, lipopolysaccharide, liposome, lipophilic polymer, polymer, polymeric microparticle, biological cell or virus. In one aspect of the invention, the conjugated substance is labeled with a plurality of dyes of the present invention, which may be the same or different.

Typically, the conjugated substance S_c is an amino acid, a peptide, a protein, a polysaccharide, a nucleotide, an oligonucleotide, a nucleic acid, a lipid, a polymeric microparticle, a biological cell, or a virus. The most preferred conjugated substances are conjugates of haptens, nucleotides, oligonucleotides, nucleic acid polymers, proteins, or polysaccharides. Most preferably, the conjugated substance is a nucleic acid, or a substance that interacts in a specific fashion with nucleic acids, such as DNA-binding proteins.

In one embodiment, the conjugated substance (S_c) is an amino acid (including those that are protected or are substituted by phosphates, carbohydrates, or C_1 to C_{22} carboxylic acids), or is a polymer of amino acids such as a peptide or protein. Preferred conjugates of peptides contain at

least five amino acids, more preferably 5 to 36 amino acids. Preferred peptides include, but are not limited to, neuropeptides, cytokines, toxins, protease substrates, and protein kinase substrates. Also preferred are peptides that serve as organelle localization peptides, that is, peptides that serve to target the conjugated dye for localization within a particular cellular substructure by cellular transport mechanisms. Preferred protein conjugates include enzymes, antibodies, lectins, glycoproteins, histones, albumins, lipoproteins, avidin, streptavidin, protein A, protein G, phycobiliproteins and other fluorescent proteins, hormones, toxins and growth factors. Typically, the conjugated protein is an antibody, an antibody fragment, avidin, streptavidin, a toxin, a lectin, or a growth factor. Preferred haptens include biotin, digoxigenin and fluorophores.

In another embodiment, the conjugated substance (S_c) is a nucleic acid base, nucleoside, nucleotide or a nucleic acid polymer, optionally containing an additional linker or spacer for attachment of a fluorophore or other ligand, such as an alkynyl linkage (US Pat. 5,047,519), an aminoallyl linkage (US Pat. 4,711,955) or other linkage. Preferably, the conjugated nucleotide is a nucleoside triphosphate or a deoxynucleoside triphosphate or a dideoxynucleoside triphosphate.

Preferred nucleic acid polymer conjugates are single- or multi-stranded, natural or synthetic DNA or RNA oligonucleotides, or DNA/RNA hybrids, or incorporating an unusual linker such as morpholine derivatized phosphates (AntiVirals, Inc., Corvallis OR), or peptide nucleic acids such as *N*-(2-aminoethyl)glycine units, where the nucleic acid contains fewer than 50 nucleotides, more typically fewer than 25 nucleotides. The dye is optionally attached via one or more purine or pyrimidine bases through an amide, ester, ether or thioether bond; or is attached to the phosphate or carbohydrate by a bond that is an ester, thioester, amide, ether or thioether. Alternatively, the dye is attached by formation of a non-covalent association of the nucleic acid and a photoreactive dye of the invention, followed by illumination, resulting in covalently bound dye. Nucleotide conjugates of the invention can be incorporated by some DNA polymerases and can be used for *in situ* hybridization and nucleic acid sequencing (e.g., US Pats. 5,332,666; 5,171,534; and 4,997,928, and WO Appl. 94/05688).

In another embodiment, the conjugated substance (S_c) is a carbohydrate or polyol that is typically a polysaccharide, such as dextran, FICOLL, heparin, glycogen, amylopectin, mannan, inulin, starch, agarose and cellulose, or is a polymer such as a poly(ethylene glycol). Preferred polysaccharide conjugates are dextran or FICOLL conjugates.

In another embodiment, the conjugated substance (S_c), is a lipid (typically having 6-25 carbons), including glycolipids, phospholipids, and sphingolipids. Alternatively, the conjugated substance is a lipid vesicle, such as a liposome, or is a lipoprotein (see below). Some lipophilic substituents are useful for facilitating transport of the conjugated dye into cells or cellular organelles.

Furthermore, the conjugates are optionally dye-conjugates of polymers, polymeric particles, polymeric microparticles including magnetic and non-magnetic microspheres, polymeric membranes, conducting and non-conducting metals and non-metals, and glass and plastic surfaces and particles.

Conjugates are typically prepared by chemical modification of a polymer that contains functional groups with suitable chemical reactivity. The conjugated polymer may be organic or inorganic, natural or synthetic. In a preferred embodiment, the dye is conjugated to a polymer matrix, such as a polymeric particle or membrane, including membranes suitable for blot assays for nucleic acids or proteins. In another embodiment, the conjugated substance is a glass or silica, which may be formed into an optical fiber or other structure. In another embodiment, the conjugated polymer is poly(ethylene glycol), a poly(acrylate) or a poly(acrylamide).

The preparation of dye conjugates using reactive dyes is well documented, e.g. by R. Haugland, MOLECULAR PROBES HANDBOOK OF FLUORESCENT PROBES AND RESEARCH CHEMICALS, Chapters 1-3 (1996); and Brinkley, BIOCONJUGATE CHEM., 3, 2 (1992).

Conjugates typically result from mixing appropriate reactive cyanine dyes and the substance to be conjugated in a suitable solvent in which both are soluble, using methods well known in the art, followed by separation of the conjugate from any unreacted dye and by-products. For those reactive dyes that are photoactivated, conjugation requires illumination of the reaction mixture to activate the reactive dye. The dye-conjugate is used in solution or lyophilized and stored for later use.

Specific binding pair members may be labeled with a dye of the invention and used to detect nucleic acids. Alternatively, the presence of the labeled specific binding pair member indicates the location of the complementary member of that specific binding pair; each specific binding pair member having an area on the surface or in a cavity which specifically binds to, and is complementary with, a particular spatial and polar organization of the other. Representative specific binding pairs are shown in Table 4.

Table 4. Representative Specific Binding Pairs

antigen	antibody
biotin	avidin (or streptavidin or anti-biotin)
IgG*	protein A or protein G
drug	drug receptor
folate	folate binding protein
toxin	toxin receptor
carbohydrate	lectin or carbohydrate receptor
peptide	peptide receptor
protein	protein receptor
enzyme substrate	enzyme
DNA (RNA)	cDNA (cRNA)†
hormone	hormone receptor

ion	chelator
-----	----------

* IgG is an immunoglobulin

† cDNA and cRNA are the complementary strands used for hybridization

Methods of Use

5 The use of the invention comprises combining a dye or dye-conjugate of the present invention with a sample that contains or is thought to contain the desired analyte, incubating the mixture of dye and sample for a time sufficient for the dye to combine with the analyte in the sample to form one or more dye-analyte complexes having a detectable fluorescent signal. The characteristics of the dye-analyte complex, including the presence, location, intensity, excitation and emission spectra,
10 fluorescence polarization, fluorescence lifetime, photobleaching rate and other physical properties of the fluorescent signal can be used to detect, differentiate, sort, quantitate, and/or analyze aspects or portions of the sample.

 The use of unsymmetrical cyanine dyes to stain nucleic acids has been well described previously (U.S. Patent No. 5,321,130 to Yue et al. (1994); U.S. Patent No. 5,410,030 to Yue et al.
15 (1995); U.S. Patent No. 5,436,134 to Haugland et al. (1995); U.S. Patent No. 5,582,977 to Yue et al. (1996); U.S. Patent No. 5,658,751 to Yue et al. (1997); and U.S. Patent No. 5,863,753 to Haugland et al. (1999)).

Staining Solution

20 Typically, the subject dye is used in an aqueous or aqueous miscible staining solution that is compatible with the sample and the intended use. The dyes have greater stability in buffered solutions than in water alone; and agents that reduce the levels of free oxygen radicals, such as β -mercaptoethanol, contribute to the stability of the dyes. When staining nucleic acids, high
25 concentrations of organic solvents, cations, and oxidizing agents also generally reduce fluorescence of the dye-nucleic acid complex, as does the ionic detergent sodium dodecyl sulfate (SDS) at concentrations $>0.01\%$. A number of staining solution additives, however, do not interfere with the fluorescence of the dye-nucleic acid complex (e.g. urea up to 8 M; CsCl up to 1 g/mL; formamide up to 50% of the solution; and sucrose up to 40%). Nonionic detergents such as Tween 20, NP40 or
30 Triton X-100 at concentration of less than or equal to 0.1%, DMSO at concentrations less than or equal to 10%, and ethanol at concentrations of less than or equal to about 10% stabilize the dye-buffer staining solution, but can interfere with staining of poly(amino acids).

 The staining solution is typically prepared by first dissolving the dye in a water-miscible organic solvent such as dimethylsulfoxide (DMSO), dimethylformamide (DMF), or a lower alcohol,
35 such as methanol or ethanol. This stock solution is typically prepared at a concentration of greater than about 100-times that used in the final staining solution, then diluted one or more times with an aqueous solvent or a buffer solution. The buffer solution may be, for example, a buffered saline

(preferably non-phosphate for some viability discrimination applications), or a Tris(hydroxymethyl)aminomethane (TRIS) buffer (preferably containing EDTA). Typically, the dye is first dissolved in 100% DMSO, and then diluted with buffer.

Where the analyte is a poly(amino acid) and the sample is a solution, or a solid or semi-solid matrix such as a blot or electrophoretic gel, the dye is preferably combined with the sample in an effective amount in the presence of a low percentage of a lipid. The amount of lipid or detergent required is typically that available from a solution of 0.05 – 2.0% sodium dodecyl sulfate (SDS). Although the dyes of the invention may stain some proteins in the absence of lipid complexation, both the association of the dye with the protein and the resulting fluorescent signal are enhanced by the presence of a lipid complexing agent. Preferably the lipid complexing agent is an amphiphilic lipid, such as a detergent.

The detergent is optionally added simultaneously with or as part of the sample or the staining mixture, or is added thereafter to the combined mixture. The detergent is any amphiphilic surface active agent or surfactant that serves to coat the poly(amino acids) (i.e. non-covalently associate with the poly(amino acid)), or is a mixture of more than one detergent. Useful detergents include non-ionic, cationic, anionic, amphoteric and fluorinated surfactants. A variety of detergents are commercially available and any detergent that is utilized in protein gel electrophoresis is a preferred detergent for the present invention. Typically, the detergent is an anionic detergent, preferably an alkyl sulfate or alkyl sulfonate salt. More preferably, the detergent is sodium dodecyl sulfate (SDS), sodium octadecyl sulfate, or sodium decyl sulfate, or a mixture thereof. Most preferably, the detergent is sodium dodecyl sulfate.

The dyes of the invention typically stain micelles, when present, so it is preferred that any detergent or detergent mixture present in the sample mixture, staining mixture, or combined mixture be present below the critical micelle concentration (CMC) for that detergent.

An effective amount of dye is the amount of dye sufficient to give a detectable fluorescence response in combination with the desired analyte. The optimal concentration and composition of the staining solution is determined by the nature of the sample (including physical, biological, biochemical and physiological properties), the nature of the dye-analyte interaction (including the transport rate of the dye to the site of the analyte), and the nature of the analysis being performed, and is determined using standard procedures, similar to those described in examples below.

Sample Types

When used to stain nucleic acids or to form conjugates of nucleic acids, the dye is combined with a sample that contains or is thought to contain a nucleic acid. The nucleic acid in the sample may be RNA or DNA, or a mixture or a hybrid thereof. Any nucleic acid is optionally single- or multiple-stranded. The nucleic acid may be a natural or synthetic polymer. The nucleic acid polymer (preferably containing at least 8 bases or base pairs) may be present as nucleic acid

fragments, oligonucleotides, or larger nucleic acid polymers with secondary or tertiary structure. The nucleic acid is optionally present in a condensed phase, such as a chromosome, or in a protein complex, such as a ribosome or nucleosome. The nucleic acid polymer optionally contains one or more modified bases or links or contains labels that are non-covalently or covalently attached. For example, the modified base is optionally a naturally occurring modified base, a known minor base, or is synthetically altered to contain an unusual linker such as morpholine derivatized phosphates, or peptide nucleic acids, or to contain a simple reactive functional group (<10 carbons) that is an aliphatic amine, carboxylic acid, alcohol, thiol or hydrazine, or to contain a fluorescent label or other hapten. The sensitivity of the dyes for polymers containing primarily modified bases and links may be diminished by interference with the binding mode.

The analyte of interest is optionally enclosed within a biological structure (i.e. an organism or a discrete unit of an organism), free in solution (including solutions that contain biological structures), immobilized in or on a solid or semi-solid material, or is extracted from a biological structure (e.g. from lysed cells, tissues, organisms or organelles). Preferably, the analyte is present in an aqueous environment in order to facilitate contact with the dye.

Typically, the analyte is a nucleic acid, and the biological structure that encloses the nucleic acid is optionally a cell or tissue, for example where the nucleic acid is present in a cell or interstitial space as a prokaryote or eukaryote microorganism, or as a virus, viroid, chromosome or organelle. Alternatively, the biological structure is not enclosed in a tissue or cell, and is present either as a virus or as a microorganism or other cell, or is present as a cellular component removed from its parent cell (e.g. a plasmid or chromosome, or a mitochondrion or nucleus or other organelle). Typically, the biological structure is an organelle, chromosome or cell that is optionally inside a eukaryote cell. The cell that is present inside a eukaryote cell is typically a parasite or other infective agent such as a bacterium, protozoa, mycoplasma or mycobacterium. Where the nucleic acid is contained in a biological structure that is a cell, the cells are viable or dead cells or a mixture thereof, i.e. the integrity of the cell membrane is optionally intact or disrupted by natural (autolytic), mechanical or chemical means or by environmental means such as changes in temperature or pressure. Alternatively, the cells are blebbing or undergoing apoptosis or necrosis or are in a cycle of growth or cell division.

Preferred cell types include but are not limited to eukaryotes, such as plant and animal cells, including pollen and gamete cells; prokaryotes, particularly bacteria; as well as yeast and other fungi, and spores. In one embodiment, the sample comprises reticulocytes. The dyes are not equally effective in staining all cell types and certain dyes are generally more permeant than others. Live cells are less permeable to the dyes than dead cells, and prokaryotes are typically less permeable than eukaryotes. Where the nucleic acids are in cells, the cells are optionally single cells, including microorganisms, or multiple cells associated with other cells in two or three dimensional layers, including multicellular organisms, embryos, tissues, biopsies, filaments, biofilms, etc.

The nucleic acids in the sample, both natural and synthetic, may be obtained from a wide

variety of sources. The nucleic acid in the sample may be present naturally, or as the result of a synthesis or experimental methodology, contamination, or a disease state. The nucleic acid may be endogenous or introduced as foreign material.

Typically, the sample containing nucleic acids is a cell or is an aqueous or aqueous miscible solution that is obtained directly from a liquid source or as a wash from a solid material (organic or inorganic) or a growth medium in which cells have been introduced for culturing or a buffer solution in which nucleic acids or biological structures have been placed for evaluation.

Alternatively, the sample is a solid, optionally a smear or scrape or a retentate removed from a liquid or vapor by filtration. The sample may be obtained from a biological fluid, such as urine, cerebrospinal fluid, blood, lymph fluids, tissue homogenate, interstitial fluid, cell extracts, mucus, saliva, sputum, stool, physiological secretions or other similar fluids. Alternatively, the sample is obtained from an environmental source such as soil, water, or air; or from an industrial source such as a waste stream, a water source, a supply line, or a production lot. Industrial sources also include fermentation media, such as from a biological reactor or food fermentation process; or foodstuffs, such as meat, grain, produce, or dairy products.

In yet another embodiment, the sample is a solid or semi-solid matrix and the nucleic acids of interest are present on or in the matrix. In one aspect of the invention, the matrix is a membrane. In another aspect, the matrix is an electrophoretic gel, such as is used for separation and characterization of nucleic acids. In another aspect, the matrix is a silicon chip or glass slide, and the nucleic acids of interest have been immobilized on the chip or slide in an array.

Where the nucleic acid is present in a solution, the sample solution can vary from one of purified or synthetic nucleic acids such as oligonucleotides to crude mixtures such as cell extracts or homogenates or other biological fluids. In some cases it is desirable to separate the nucleic acids from a mixture of biomolecules or fluids in the solution such as by various chromatographic and electrophoretic techniques. Alternatively, mixtures of nucleic acids may be treated with RNase or DNase so that the polymer that is not degraded in the presence of the nuclease can be discriminated from degradation products using the subject dyes.

Where the sample is a lipid-complexed protein, the lipid-complexed protein is preferentially not associated with a biological cell but is free in solution or is immobilized on a solid or semi-solid matrix or is in an electrophoretic matrix or chamber, such as one used for gel or capillary electrophoresis.

Where the analyte is a poly(amino acid), the analyte is optionally a synthetic or naturally occurring poly(amino acid), such as a peptide, polypeptide or protein. Poly(amino acids) that are stained and analyzed according to the present method optionally incorporate non-peptide regions (covalently or non-covalently) including lipid (lipopeptides and lipoproteins), phosphate (phosphopeptides and phosphoproteins), and/or carbohydrate (glycopeptides and glycoproteins) regions; or incorporate metal chelates or other prosthetic groups or non-standard side chains; or are multi-subunit complexes, or incorporate other organic or biological substances, such as nucleic acids.

The poly(amino acids) are optionally relatively homogeneous or heterogeneous mixtures of poly(amino acids). In one aspect of the invention the poly(amino acids) are enzymes, antibodies, transcription factors, secreted proteins, structural proteins, or binding factors, or combinations thereof. The poly(amino acids) in the sample mixture are optionally covalently or non-covalently bound to a solid surface, such as a glass slide, multi-well plate, microtiter plate well, plastic pin or bead, or semiconductor material, or they are unbound. The staining of a poly(amino acid) that is bound to an analyte on a solid surface indicates the presence of the analyte as well as that of the poly(amino acid).

The poly(amino acids) are optionally unmodified, or have been treated with a reagent so as to enhance or decrease the mobility of the poly(amino acid) in an electrophoretic gel. Such reagents may modify poly(amino acids) by complexing with the peptide (to decrease migration), by cleaving selected peptide bonds (to increase migration of the resulting fragments), by changing the relative charge on the protein (as by phosphorylation or dephosphorylation) or by covalent coupling of a constituent such as occurs during glycosylation. The presence or interaction of such a reagent in the sample mixture is detected by the change in electrophoretic mobility of the treated poly(amino acids), relative to untreated poly(amino acids) having the same original composition, so that the distribution of the dye-poly(amino acid) complex indicates the presence of another analyte.

Typically the poly(amino acids) in the sample mixture have a molecular weight greater than about 500 daltons. More typically the poly(amino acids) are more than 800 daltons. Smaller polymers of amino acids (in the <1000 dalton range) are generally difficult to separate from the detergent front on denaturing gels, and typically do not adhere to filter membranes, but are still readily detected in solution. There is no precise upper limit on the size of the poly(amino acids), except that they can not be so bulky that they precipitate out of solution. Poly(amino acids) greater than about 200,000 daltons are generally not effectively resolved with current gel technology. In one embodiment of the invention, the poly(amino acids) present are a mixture of poly(amino acids) of different molecular weights that are used as molecular weight standards. A typical such mixture contains equal mass quantities of myosin, β -galactosidase, phosphorylase B, bovine serum albumin, ovalbumin, carbonic anhydrase, trypsin inhibitor, lysozyme and aprotinin.

Where the sample mixture is an aqueous solution, the poly(amino acids) of the sample mixture are typically present in a concentration of 10 ng/mL - 50 μ g/mL, more preferably in a concentration of 30 ng/mL - 10 μ g/mL, most preferably in a concentration of 50 ng/mL - 5 μ g/mL. Where the sample mixture is an electrophoretic gel, the poly(amino acids) of the sample mixture are typically present in a concentration of 1 ng/band - 4 μ g/band.

The poly(amino acids) are obtained from a variety of sources; such sources include biological fermentation media and automated protein synthesizers, as well as prokaryotic cells, eukaryotic cells, virus particles, tissues, and biological fluids. Suitable biological fluids include, but are not limited to, urine, cerebrospinal fluid, blood, lymph fluids, interstitial fluid, cell extracts, mucus, saliva, sputum, stool, physiological or cell secretions or other similar fluids.

Depending on the source of the sample mixture, it optionally contains discrete biological ingredients other than the desired poly(amino acids), including poly(amino acids) other than those desired, amino acids, nucleic acids, carbohydrates, and lipids. In one aspect of the invention, the poly(amino acids) in the sample mixture are separated from each other or from other ingredients in the sample by mobility (e.g. electrophoretic gel or capillary) or by size (e.g. centrifugation, pelleting or density gradient), or by binding affinity (e.g. to a filter membrane) in the course of the method. In another aspect of the invention, the sample mixture thought to contain the poly(amino acids) has undergone separation. In yet another aspect of the invention, the poly(amino acids) are not separated. Although lipid assemblies such as intact or fragmented biological membranes (e.g. membranes of cells and organelles), liposomes, or detergent micelles, and other lipids are optionally present in the sample mixture; the presence of large amounts of lipids, particularly lipid assemblies, increases background labeling due to non-specific staining. Intact or fragmented biological membranes in the sample mixture are preferably removed, destroyed or dispersed prior to or in the course of labeling with this method. Typically treatment of the sample mixture by standard methods to remove some or all of such lipids, such as ammonium sulfate precipitation, solvent extraction or trichloroacetic acid precipitation is used. Alternatively or additionally, lipids are removed in the course of labeling the poly(amino acids) such as by electrophoretic separation or other separation techniques (e.g. centrifugation, including gradients), or are disrupted or dispersed below the concentration at which they assemble into micelles (critical micelle concentration) by mechanical means such as sonication. Naturally occurring lipids that are present below their critical micelle concentration are optionally used as a detergent for the purposes of the present invention. Typically, the sample mixture is essentially cell-free. This method is not effective for detecting proteins that remain in cells or are associated with biological membranes.

The source and type of sample, as well as the use of the dye, will determine which dye characteristics will be most useful for staining a particular sample. For most applications, dyes are selected to give a quantum yield greater than about 0.1, more usefully 0.2 or 0.3, preferably greater than 0.5, when associated with an analyte; preferably the dyes have a quantum yield < 0.02 and more preferably < 0.01 or < 0.005 when present in solution and not associated with an analyte. Preferably, upon associating with an analyte, the dye of the invention will exhibit a fluorescence enhancement greater than about 50 fold, preferably greater than 100 fold, more preferably greater than 200 fold and most preferably greater than 500 fold. Where the fluorescence of the dye-analyte complex or dye conjugate is detected utilizing sustained high intensity illumination (e.g. microscopy), dyes with a rate of photobleaching lower than commonly used dyes (e.g. fluorescein) are preferred, particularly for use in live cells. Where the dye must penetrate cell membranes or a gel, more permeant dyes are preferred, although some cells readily take up dyes that are shown to be impermeant to other cells by means other than passive diffusion across cell-membranes, e.g. by phagocytosis or other types of ingestion. Dyes that rapidly and readily penetrate cells do not necessarily rapidly penetrate gels. In applications where the nucleic acids are stained on a gel, the dye is also selected to have a relatively

high binding affinity (preferably $K_d < 10^{-6}$ M); whereas in applications where the nucleic acid will be prestained prior to undergoing a separation step, such as gel or capillary electrophoresis, even higher binding affinity (preferably $K_d < 10^{-8}$ M) is preferred to ensure good separation. In staining nucleic acids in solution, high binding affinity translates into greater sensitivity to small amounts of nucleic acid, but dyes with a moderate binding affinity (preferably 10^{-6} M $< K_d < 10^{-8}$ M) are more effective over a greater dynamic range. The photostability, binding affinity, quantum yield, and fluorescence enhancement of dyes are determined according to standard methods known in the art.

Formation of the Dye-Analyte Complex

The sample is combined with the staining solution by any means that facilitates contact between the dye and the analyte. Typically the contact occurs through simple mixing, as in the case where the sample is a solution. A staining solution containing the dye may be added to the analyte solution directly or may contact the analyte solution in a liquid medium, or on an inert matrix. Suitable supports also include, but are not limited to, polymeric microparticles (including paramagnetic microparticles), polyacrylamide and agarose gels, nitrocellulose filters, computer chips (such as silicon chips), natural and synthetic membranes, liposomes and alginate hydrogels, and glass (including optical filters), and other silica-based and plastic support. The dye is optionally combined with the analyte solution prior to a separation step, during separation, or after the nucleic acids or lipid-complexed proteins undergo separation. Alternatively, the dye is combined with an inert matrix or solution in a capillary prior to addition of the analyte solution, as in pre-cast gels, capillary electrophoresis or preformed density or sedimentation gradients.

Combination of the dye with a lipid-complexed proteins is facilitated when the proteins are first heated in the presence of detergent, including to temperatures in excess of 90 °C. This heating step optionally occurs in the presence of the dye of the invention, although exposure to elevated temperatures may effect the stability of the dye.

Where the analyte is enclosed in a biological structure, as is typical for nucleic acids, the sample is typically incubated with the dye. Any technique that is suitable for transporting the dye into the biological structure is a valid method of combining the sample with the subject dye, including active transport, chemical transport agents, or physical disruption of the cell membranes. Preferably, the methods for staining cause minimal disruption of the viability of the cell and integrity of cell or intracellular membranes. Alternatively, the cells are fixed and treated with routine histochemical or cytochemical procedures, particularly where pathogenic organisms are suspected to be present. The cells are typically fixed immediately after staining with an aldehyde fixative that keeps the dye in the cells. In some cases, live or dead cells may be fixed prior to staining without substantially increasing cell membrane permeability of previously live cells so that only cells that were dead prior to fixation stain with a cell-impermeant dye.

The sample is combined with the dye for a time sufficient to form the fluorescent dye-analyte

complex, preferably the minimum time required to give a high signal-to-background ratio. Optimal staining with a particular dye is dependent upon the physical and chemical nature of the individual sample and the sample medium, as well as the property being assessed. For example, where the dye is chosen to be selective for a particular nucleic acid polymer or type of cell, the optimal time is usually the minimum time required to achieve the highest signal on that polymer or type of cell, with little to no signal from other nucleic acids or other cell types. Over time, undesirable staining may occur as even very low rates of diffusion may transport small amounts of the very sensitive dyes into other cell types, or staining selectivity may be lost as the cell membranes degrade, or as nucleases degrade nucleic acid polymers in cell-free systems.

- 10 Preferably, the dye is combined with the sample at a temperature optimal for biological activity of the analyte within the operating parameters of the dyes (usually between 5 °C and 50 °C, with reduced stability of the dyes at higher temperatures), typically at about room temperature (23 °C). At room temperature, detectable fluorescence in a solution of nucleic acids is essentially instantaneous depending on the sensitivity of the instrumentation that is used; fluorescence in solutions is generally visible by eye within 5 seconds after the dye is added, and is generally measurable within 2 to 5 minutes, although reaching equilibrium staining may take longer. In particular, staining of lipid-complexed proteins in solution may be slower than equivalent staining of nucleic acids. Where a biological process is underway during *in vitro* analysis (e.g. *in vitro* transcription, replication, splicing, or recombination), the rapid labeling that occurs with the subject dyes avoids perturbation of the biological system that is being observed. Gel staining at room temperature usually takes from 5 minutes to 2 hours depending on the thickness of the gel and the percentage of agarose or polyacrylamide, as well as the degree of cross-linking. Typically, post-stained minigels stain to equilibrium in 20–45 minutes. For cells and other biological structures, transport of dyes across membranes is required whether the membranes are intact or disrupted.
- 25 The relative permeability of the cell membrane to the dyes is determined empirically, e.g. by comparison with staining profiles or staining patterns of killed cells. The dye with the desired degree of permeability, and a high absorbance and quantum yield when bound to nucleic acids or lipid-complexed proteins, is selected to be combined with the sample.

30 *Fluorescence of the Dye-Analyte Complex*

- The presence, location, and distribution of nucleic acid or lipid-complexed protein are detected using the spectral properties of the fluorescent dye-analyte complex. Spectral properties means any parameter that may be used to characterize the excitation or emission of the dye-nucleic acid complex including absorption and emission wavelengths, fluorescence polarization, fluorescence lifetime, fluorescence intensity, quantum yield, and fluorescence enhancement. Individual dyes may be selected for use with a specific excitation source or detection filter. For example, complexes formed with dyes having a monomethine moiety ($n=0$) generally match their primary excitation band

with the 532 nm excitation line of the frequency-doubled Nd-Yag laser, the 543 nm excitation line of the green He-Ne laser, the strong 546 nm emission of the Hg-arc lamp and sometimes the 568 nm excitation line of the Kr laser; whereas those with dyes with a trimethine moiety ($n=1$) primarily tend to match long wavelength excitation sources such as the orange HeNe laser (594 nm), the red HeNe laser (633 nm), the Kr laser (568 or 647 nm) and certain laser diodes, in particular the 635 nm laser diode; and complexes formed with dyes having a pentamethine moiety ($n=2$) primarily match very long excitation sources such as laser diodes or light emitting diodes (LEDs). In addition to the primary excitation peak in the visible range, the dye-nucleic acid complexes and dye-lipid-complexed protein complexes of the invention have a secondary absorption peak that permits excitation with UV illumination. Dyes with $n = 1$ and $n = 2$ typically form complexes that permit excitation beyond 600 nm.

Typically, the sample is excited by a light source capable of producing light at or near the wavelength of maximum absorption of the fluorescent complex, and the fluorescence of the complex is detected qualitatively or quantitatively by detection of the resultant light emission at a wavelength of greater than about 450 nm, preferably greater than about 480 nm, more preferably at greater than about 500 nm. The emission is detected by visual inspection or by instrumental methods well known in the art. Many instruments are capable of utilizing the fluorescent signal to sort and quantitate cells or quantitate the nucleic acids. Dyes can be selected to have emission bands that match commercially available filter sets such as that for fluorescein, tetramethylrhodamine or for detecting multiple fluorophores with several excitation and emission bands.

Use of the Complex

The fluorescent dye-analyte complex is useful in essentially any application previously described for other fluorescent nucleic acid or protein stains (for example as described in U.S. Patent No. 5,436,134 to Haugland et al. (1995); U.S. Patent No. 5,445,946 to Roth et al. (1995); U.S. Patent No. 5,534,416 to Millard et al. (1996); U.S. Patent No. 5,616,502 to Haugland et al. (1997)).

Once the dye-analyte complex is formed, its presence may be detected and used as an indicator of the presence, location, or type of analyte in the sample, or as a basis for sorting cells, or as a key to characterizing the sample or cells in the sample. Such characterization may be enhanced by the use of additional reagents, including fluorescent reagents. The amount of analyte in a sample can also be quantified by comparison with known relationships between the fluorescence of the dye-analyte complex and concentration of analyte in the sample.

In addition, the staining profile that results from formation of the dye-analyte complex may be indicative of one or more characteristics of the sample. By staining profile is meant the shape, location, distribution, and spectral properties of the profile of fluorescent signals resulting from excitation of the fluorescent dye-analyte complexes. The sample can be characterized simply by

staining the sample and detecting the staining profile that is indicative of a characteristic of the sample. More effective characterization is achieved by utilizing a dye that is selective for a certain characteristic of the sample being evaluated or by utilizing an additional reagent (as described below), where the additional reagent is selective for the same characteristic to a greater or lesser extent or where the additional reagent is selective for a different characteristic of the same sample.

In one embodiment of the invention, where the dye is selected to be membrane permeable or relatively impermeant to cell membranes, the staining profile that results from the formation of the dye-analyte complex is indicative of the integrity of the cell membrane, which in turn is indicative of cell viability. In combination with a cell permeant dye of the invention, this allows the differentiation of viable cells from dead cells.

In a further embodiment of the invention, the shape and distribution of the staining profile of dye-analyte complexes is indicative of the type of cell or biological structure that contains the stained nucleic acids. Cells may be discriminated by eye based on the visual fluorescent signal or be discriminated by instrumentation as described above, based on the spectral properties of the fluorescent signal. Typically the staining profile used to characterize the sample is indicative of the presence, shape, or location of organelles or of cells, where the cells are located in a biological fluid, in a tissue, or in other cells.

In another aspect of the invention, the dye-analyte complex is used as a fluorescent tracer or as a probe for the presence of a second analyte. In one aspect of the invention, the dye-analyte complex is used as a size or mobility standard, such as in electrophoresis or flow cytometry. Alternatively, the fluorescent signal that results from the interaction of the dye with the first analyte can be used to detect or quantitate the activity or presence of other molecules that interact with the first analyte.

Applications of chemically reactive cyanine dyes

The reactive dyes of the invention are particularly useful for immobilizing the dye on a surface or substrate, such as a polymeric microparticle, polymeric membrane, fiber, or silicon chip. In this embodiment, the dye is useful as a capture reagent for purification or detection of an analyte, particularly nucleic acids. Alternatively, the immobilized dyes are useful for moving associated analytes from one environment to another via mechanical means. Where the subject dyes are attached to a surface, the surface can also function as a quantitative or qualitative indicator of an analyte in solution, such as a test strip or dipstick.

The reactive dyes of the invention are also useful as detection reagents during the separation and purification of nucleic acids. For example the dyes of the invention can be conjugated to agar or agarose and used to cast plates or gels that are then useful for spot assays to quantitate nucleic acids. The ability of the reactive dyes of the invention to form stable covalent bonds with a variety of substrates allows the attachment of nucleic acid stains to electrophoretic gel matrices (producing

very stable and uniformly stained pre-prepared gels).

Alternatively, where nucleic acids are analyzed using capillary electrophoresis, the dyes of the invention may be conjugated in a small "band" or region in the capillary, resulting in detection of nucleic acids with high sensitivity, as the detecting reagent is concentrated into a small volume, allowing efficient illumination using a laser or other excitation source. Where a conjugated dye is used in this fashion, the dye is optionally utilized only to capture the nucleic acids, with detection accomplished by another detection reagent, or the fluorescent enhancement upon binding nucleic acids is utilized to detect the capture event itself.

Where the dye is covalently bound to a substrate, such as a polymeric microparticle or membrane, the nucleic acids that are associated with the bound dye can be used as templates for translation and replication. Where the dye of the invention possesses a particularly high affinity for nucleic acids, passing a solution containing nucleic acids over a suitable labeled polymer matrix results in depletion of nucleic acids from the solution. The complexed nucleic acids can then be utilized in place or extracted from the matrix for further analysis or utilization.

Alternatively, a reactive dye of the invention can be associated with purified nucleic acids and covalently linked to the nucleic acids, which are then transferred to a membrane by blotting, and covalently bound to the polymeric membrane, resulting in a permanently labeled blot.

The dyes are optionally covalently bound to a molecule, such as a dextran, which is normally excluded from live cells. When dead or permeabilized cells then take up these molecules, the bound dye interacts with intracellular nucleic acids, giving rise to fluorescence. Similarly, the dye-conjugates of the invention possess utility for retaining conjugated substances within cells. This is particularly useful for conjugated substances that are typically excreted from living cells relatively quickly, such as small organic molecules or by-products of enzyme activity.

The dye is optionally conjugated to a substance selected such that the resulting conjugate has substantially different physical properties than those of the unbound dye, for example, conjugation of a dye of the invention to a polysaccharide or a poly(ethylene glycol) polymer to influence solubility, cellular retention, or ability to bind analytes.

Additional applications of chemically reactive nucleic acid stains are described in U.S. Patent No. 5,863,753 to Haugland et al., 1999.

Applications of covalently labeled nucleic acids

The dyes of the invention are useful for labeling unmodified nucleic acids covalently (typically using a photoreactive dye) so that the labeled nucleic acid retains its label through capillary transfer or electrophoretic transfer to filter membranes and subsequent hybridization (for example as in Southern blotting). The dyes are also useful in Southwestern analysis, wherein the dye is first coupled covalently to a nucleic acid, and the nucleic acid is then used to probe a Western blot containing putative nucleic acid-binding proteins. Fluorescence enhancement indicates

locations on the blot membrane where the nucleic acid has been captured by the immobilized protein. Conjugates of proteins that do not interact specifically with nucleic acids do not exhibit similar fluorescence enhancement when used at similar concentrations, and in the absence of detergent. Similar interactions are useful for detecting immobilized DNA. Alternatively, where the protein is
5 labeled with a second reagent, colocalization of that reagent and the dye of the invention indicates an interaction between the dye and the protein. This type of assay is also useful for analyzing nucleic acid-binding drugs.

Where the dyes of the invention are used to covalently label nucleic acids, the labeled nucleic acid is useful as a probe to detect interactions between nucleic acid-binding drugs or proteins, where
10 the drug or protein has been labeled with a second fluorophore or a fluorescence quenching agent. Binding of the nucleic acid with the drug or protein results in loss of fluorescence. In this way, the nucleic acid-binding drug or protein can be quantitated, and the presence or absence of either inhibitors or enhancers of nucleic acid binding could be identified. This application is also useful for *in vivo* or *in vitro* studies, for example in the study of interactions between SSB (single strand
15 binding protein) and single stranded DNA, histones and double stranded DNA, sequence specific binding factors and their cognate sequences, or mismatch repair enzymes and mismatch regions of DNA hybrids.

Dye-labeled nucleic acids are useful for monitoring transfection into cells, either by the labeled nucleic acid itself, or where another molecule is cotransfected and the labeled nucleic acid is
20 simply a tracer. The amount of labeled nucleic acid in a cell could be used to standardize the copy number of transiently transfected plasmids in reporter gene assays, such as chloramphenicol acetyltransferase assays (CAT assays).

Dye-conjugates of nucleic acids possess utility for detecting hybridization, as the dye-conjugate typically exhibits a change in fluorescence enhancement upon binding to a complementary
25 strand of nucleic acid. Dye-labeled nucleic acids are also useful for following triplex formation, or strand invasion, during DNA recombination. If two dyes capable of energy transfer are used, then real-time measurements of hybridization or strand invasion/displacement may be made. In particular both the interactions of antisense oligonucleotides with nucleic acids and RNA splicing could be followed using this methodology.

30 Where the dye is used to covalently label a nucleic acid, the nucleic acid could then be ligated to another unlabeled nucleic acid, so that even if the labeled nucleic acid fragment is unable to hybridize or bind proteins efficiently, the unlabeled portion retains full biological activity. However, the nucleic acid is readily detectable due to the presence of the attached dye.

The dyes of the invention also serve as haptens for secondary detection. The use of labeled
35 antibodies directed against the dyes of the invention allows for signal amplification in the detection of either a conjugated substance, or a labeled nucleic acid. Alternatively, where the conjugated substance is a specific binding pair member, the specific binding pair member may be used to amplify the detectable signal of the cyanine dye, typically by immunological methods. In this

embodiment, the conjugated substance is typically a hapten, biotin or digoxigenin or a non nucleic acid-binding dye. The dye-conjugate forms a nucleic acid-dye complex, producing enhancement of its fluorescence. The complex is then labeled with the complement of the specific binding pair member, which is typically labeled with a fluorophore, producing an additional fluorescent enhancement.

5

Additional Reagents

The dyes of the invention can be used in conjunction with one or more additional reagents that are separately detectable. The additional reagents may be used separately, or selected to give a detectable response that is different from that of other reagents used in combination with the subject dyes. Preferably the additional reagent or reagents are fluorescent and have different spectral properties from those of the dye-analyte complex. Differences in spectral properties include, but are not limited to, a difference in excitation maxima, a difference in emission maxima, a difference in fluorescence lifetimes, a difference in fluorescence emission intensity at the same excitation wavelength or at a different wavelength, a difference in absorptivity, a difference in fluorescence polarization, a difference in fluorescence enhancement in combination with target materials, or combinations thereof. Dyes that form complexes that permit excitation beyond 600 nm can be used in combination with commonly used fluorescent antibodies such as those labeled with fluorescein isothiocyanate or phycoerythrin.

The detectably different dye is optionally one of the dyes of the invention having different spectral properties and different selectivity. In one aspect of the invention, the dye-analyte complex and the additional detection reagents possess visibly different emission spectra, generally having emission maxima separated by >10 nm, preferably >20 nm, more preferably >50 nm. Simultaneous excitation of all fluorescent reagents may require excitation of the sample at a wavelength that is suboptimal for each reagent individually, but optimal for the combination of reagents. Alternatively, the additional reagent(s) can be simultaneously or sequentially excited at a wavelength that is different from that used to excite the subject dye-analyte complex. In yet another alternative, one or more additional reagents are used to quench or partially quench the fluorescence of the dye-analyte complex, such as by adding a second reagent to improve the selectivity for a particular nucleic acid or the AT/GC selectivity.

The additional dyes are optionally used to differentiate cells or cell-free samples containing the desired analyte according to size, shape, metabolic state, physiological condition, genotype, or other biological parameters or combinations thereof. The additional reagent is optionally selective for a particular characteristic of the sample for use in conjunction with a non-selective reagent for the same characteristic, or is selective for one characteristic of the sample for use in conjunction with a reagent that is selective for another characteristic of the sample. In one aspect of the invention, the additional dye or dyes are metabolized intracellularly to give a fluorescent product inside certain cells but not inside other cells, so that the fluorescence response of the cyanine dye of the invention

predominates only where such metabolic process is not taking place. Alternatively, the additional dye or dyes are specific for some external component of the cell such as cell surface proteins or receptors, e.g. fluorescent lectins or antibodies. In yet another aspect of the invention, the additional dye or dyes actively or passively cross the cell membrane and are used to indicate the integrity or functioning of the cell membrane (e.g. calcein AM or BCECF AM). In another aspect, the additional reagents bind selectively to AT-rich nucleic acids and are used to indicate chromosome banding. In another aspect of the invention, the additional reagent is an organelle stain, i.e. a stain that is selective for a particular organelle, for example the additional reagent(s) may be selected for potential sensitive uptake into the mitochondria (for example as described in U.S. Patent No. 5,459,268 to Haugland et al. (1995)) or for uptake due to pH gradient in an organelle of a live cell (U.S. Patent No. 5,869,689 to Zhang et al. (1999)).

The additional dyes are added to the sample being analyzed to be present in an effective amount, with the optimal concentration of dye determined by standard procedures generally known in the art. Each dye is optionally prepared in a separate solution or combined in one solution, depending on the intended use. After illumination of the dyed cells at a suitable wavelength, as above, the cells are analyzed according to their fluorescence response to the illumination. In addition, the differential fluorescence response can be used as a basis for sorting the cells or nucleic acids for further analysis or experimentation. For example, all cells that "survive" a certain procedure are sorted, or all cells of a certain type in a sample are sorted. The cells can be sorted manually or using an automated technique such as flow cytometry, according to the procedures known in the art, such as in U.S. patent 4,665,024 to Mansour, et al. (1987).

Kits

In one aspect of the invention, the cyanine dyes of the invention are incorporated into a kit for commercial use. In one embodiment, the kit comprises a selection of dyes of the invention, typically present as a concentrated stock solution in a non-aqueous solvent, preferably DMSO. Where the kit is a "sampler" kit of cyanine dyes, the kit comprises 2-8 distinct cyanine dyes, preferably 4-6 distinct cyanine dyes.

In another embodiment of the invention, the reagent kit comprises a stock solution of the dye of the invention, typically present in a DMSO solution, a buffer suitable for dilution of the stock solution, and optionally further comprises a standard or an additional detection reagent, or both. The standard is optionally one or more nucleic acids (for nucleic acid detection/quantification), or one or more proteins (for protein detection/quantification). The additional detection reagent is typically an organelle stain, a labeled immunoreagent, a drug, or an enzyme.

In yet another embodiment of the invention, the reagent kit comprises a stock solution of the dye of the invention, typically present in a DMSO solution, a buffer suitable for dilution of the stock solution, a silicon chip or glass slide, and nucleic acid standards.

Synthesis of the Dyes and Dye-Conjugates of the Invention

A useful synthetic route to the dyes of the present invention can be described in three parts, following the natural breakdown in the description of the compounds. In general, the synthesis of these dyes requires three precursors: the appropriate azabenzazolium, or polyazabenzazolium salt; the appropriate pyridine, quinoline, pyridinium or quinolinium; and (where $n = 1$ or 2) a source for the methine spacer. Typically each component is selected so as to incorporate the appropriate chemical substituents, or functional groups that can be converted to the appropriate substituents. The chemistry that is required to prepare and combine these precursors so as to yield any of the subject derivatives is generally well understood by one skilled in the art (see U.S. Patent No. 5,436,134 to Haugland et al. (1995); U.S. Patent No. 5,656,449 to Yue (1997); U.S. Patent No. 5,658,751 to Yue et al. (1997), U.S. Patent No. 5,863,753 to Haugland et al. (1999)). Although there are many possible variations that may yield an equivalent result, we provide herein some useful general methods for their synthesis and incorporation of chemical modifications.

The azabenzazolium or polyazabenzazolium moiety

A wide variety of derivatives suitable for the preparation of the dyes of the invention have been previously described (see, for example, Brooker, et al., J. AM. CHEM. SOC., **64**, 199 (1942); Heravi, et al., INDIAN J. CHEM. **36B**, 1025 (1997); Smith et al. SULFUR LETTERS **17**, 197 (1994); Chu-Moyer et al. J. ORG. CHEM. **60**, 5721 (1995); Turner, J. ORG. CHEM. **48**, 3401 (1983); Couture et al. J. HETEROCYCLIC CHEM. **24**, 1765 (1987); Petric et al. J. HETEROCYCLIC CHEM. **14**, 1045, (1977); Barlin et al. AUST. J. CHEM., **37**, 1729 (1984); Saikachi et al. CHEM. & PHARM. BULL. **9**, 941 (1961); Barlin AUST. J. CHEM. **36**, 983 (1983); Foye et al., J. PHARM. SCI. **64**, 1371 (1975); Khanna et al. J. ORG. CHEM. **60**, 960 (1995)); British Patent No. 870,753 to Ficken et al. (1961); Ficken et al., "Diazaindenes and Their Quaternary Salts-Part I" pp 3202-3212 (1959); Ficken et al., "Diazaindenes and Their Quaternary Salts-Part II" pp 584-588 (1961); These synthetic precursors have the common structure:

where A, X, R^2 , R^{15} - R^{17} , α , and β have been defined previously. If X is O, the precursor compound is an aza- or polyaza-benzoxazolium; if X is S it is an aza- or polyaza-benzothiazolium; if X

is Se it is an aza- or polyaza-benzoselenazolium; if X is N or an alkyl-substituted N it is an aza- or polyaza-benzimidazolium; and if X is CR¹⁶R¹⁷ then it is an aza- or polyaza-indolinium derivative. Commonly R¹⁶ and R¹⁷ are both methyl. However, methods for preparing compounds where R¹⁶ and R¹⁷ are not methyl are known (Smith et al., SULFUR LETTERS, 18, 79 (1995); Smith et al., CHEM
5 INDUSTRY, 9, 302 (1988); Couture et al. HETEROCYCLES 22, 1383 (1984)).

The substituents on the aromatic carbons of the aza-benzazolium moiety are typically incorporated in the parent aza- or polyaza-benzazole molecule prior to quaternization with an alkylating agent. However, such substituents may also be incorporated during the synthesis of the aza-benzazole moiety (Examples 1-4). R² is usually obtained by alkylation of the parent heterocycle
10 with an alkylating agent R²-Z, where R² is a substituent as described above, in particular where R² is an alkyl group having 1-6 carbons, that is optionally substituted by sulfonate, carboxy, amino, or a chemically reactive group, or a precursor necessary for formation of a TAIL moiety, or attachment of a BRIDGE precursor, or second dimer subunit. Z of the alkylating agent is an electronegative group that frequently becomes the counterion on the resultant dye, Ψ. The counterion may be exchanged
15 for another counterion by methods known in the art, such as the use of ion exchange resins or by precipitation. Selected examples of R²-Z include methyl iodide, diethyl sulfate, hexyl p-toluenesulfonate, sulfopropyl iodide, and sulfobutyl iodide. Preferred R²-Z are compounds that yield R² = methyl, such as methyl iodide, methyl methanesulfonate, dimethyl sulfate, methyl trifluoromethanesulfonate or methyl p-toluenesulfonate.

20 D is a substituent whose nature is determined by the synthetic method utilized to couple the azabenzazolium or polyazabenzazolium precursor with the desired precursor of the second heterocyclic ring system. When n = 0, D is typically alkylthio, commonly methylthio, or A is chloro, bromo or iodo. When n = 1 or 2, A is methyl. Only in the case of D = methyl is any part of D incorporated in the final compound.

25 The aza-benzoxazolium precursor compounds wherein X = O have not been previously described.

The preparation of useful intermediates for the synthesis of the dyes of the invention via acetylation of a 2-amino-3-hydroxypyridine has similarly not been previously described (Examples 5
30 and 21).

The second heterocyclic ring system

A variety of compounds useful as precursors for the second heterocyclic ring system are available. Compounds containing the quinolinium moiety in this invention differ from those that
35 contain a single pyridinium ring only in the presence of an additional aromatic ring containing four carbon atoms that is fused at the R⁶ and R⁷ positions of the parent structure. Except where reference is to a specific pyridine or pyridinium salt, it is understood that mention of pyridines or pyridinium salts encompasses benzopyridines and benzopyridinium salts, which are formally called

quinolines or quinolinium salts. Mention of quinolines and quinolinium salts refer only to structures containing at least two fused aromatic rings. Similarly, pyridine and quinoline precursors are not formally charged, and are not substituted by an R⁵ substituent.

In the synthesis of the dyes of the invention, the second heterocyclic precursor is usually appropriately substituted. Alternatively, substituents can be incorporated into the precursor structure subsequent to attachment of the azabenzazolum portion of the dye. One of the substituents that may be incorporated before or after reaction with the azabenzazolum or polyazabenzazolum precursor is TAIL.

There exist two major structural distinctions within the family of dyes described in the invention that are related to the point of attachment of the second heterocyclic ring system. In one case (where m = 0 and p = 1) the position of attachment places the methine moiety adjacent to the ring nitrogen ("2-substituted"). In the more common case (where m = 1 and p = 0) the position of the nitrogen atom is *para* to the point of attachment ("4-substituted").

Typically the required pyridinium salt precursor has the structure

and the quinolinium salt precursor has the general structure

with the substituents as defined previously. At all times, the ring is a 6-membered pyridinium-based heterocycle.

When n = 0, B is methyl, or B is chloro, bromo or iodo. When n = 1 or 2, B is methyl. Only when n = 1 or n = 2 is any part of B incorporated in the final compound.

There are several general published methods for the synthesis of derivatives of pyridinium and pyridine, including those derivatives having substituents at any available position, including substitutions that are TAIL or that can be converted to TAIL before or after reaction with the azabenzazolum or polyazabenzazolum portion to form the dye core structure (see U.S. Patent No. 5,436,134, U.S. Patent No. 5,658,751, and U.S. Patent No. 5,863,753). Typically, desired substituents are incorporated via alkylation of the nitrogen atom of an appropriately substituted quinoline, or R⁵ substituents that are aryl or heteroaryl are incorporated by an Ullmann reaction of

aniline or a substituted aniline or of a pyridone or quinolone derivative (pyridone and quinolone precursors may also be prepared by an Ullmann reaction of the appropriately substituted precursor if the nitrogen atom is hydrogen-substituted).

Pyridone and quinolone intermediates containing a non-hydrogen group at R⁵ are particularly important precursors to a wide variety of other pyridinium and quinolinium salts that are substituted at R⁴. In particular a salt is formed by treatment of the appropriate pyridone or quinolone with a strong chlorinating agent such as PCl₅, POCl₃ or SOCl₂, for instance in the reaction below. Similarly, a sulfonate can be substituted at R⁴ by treating the pyridone or quinolone with the appropriate sulfonic acid anhydride.

Halogen displacement

The reactivity of the 2-halogenated pyridinium or quinolinium intermediate offers a variety of synthetic methods for attachment of various substituents at the 2-position, including TAIL moieties, TAIL precursors, -L-R_n moieties, and BRIDGE precursors. However, the reactivity of the 2-halo derivatives is preserved even after conjugation with the benzazolium precursor, enabling conversion of the resulting dye in which R⁴ is halogen into the appropriate alkoxy, amino and thiolate analogs, as described for the pyridinium and quinolinium precursors. Of particular utility for the dyes of the present invention is the displacement of a 2-chloro substituent by amines.

Additionally, the 2-oxo group of pyridone or quinolone precursors can be chemically reduced to derivatives in which R⁴ is H using a variety of reagents including DIBAL-H (diisobutylaluminum hydride).

The methine moiety

The number of methine groups that connect the two heterocyclic ring systems is determined by the specific synthetic reagents used in the synthesis. When n = 0, the synthesis of monomethine dyes commonly uses a combination of reagents where the methine carbon atom results from either D on the azabenzazolium or polyazabenzazolium salt or B on the pyridinium salt being methyl and the other of D or B being a reactive "leaving group" that is typically methylthio or chloro, but that can be any leaving group that provides sufficient reactivity to complete the reaction, as described by Brooker et al., *supra*. Whether D or B is methyl depends primarily on the relative ease of synthesis of the requisite precursor salts. Because 2-methyl and 4-methyl pyridines are usually easier to prepare than their corresponding methylthio analogs, monomethine dyes are typically prepared from precursors in which D = methylthio and B = methyl. The condensing reagent in the case of monomethine dyes is typically a weak base such as triethylamine or diisopropylethylamine.

To synthesize trimethine dyes (n = 1) both D and B are methyl. In this case the additional methine carbon is provided by a reagent such as diphenylformamidine, N-methylformanilide or ethyl

orthoformate. Because under certain reaction conditions these same reagents can yield symmetrical cyanine dyes that incorporate two moles of a single quaternary salt, it is important to use the proper synthetic conditions, and a suitable ratio of the carbon-providing reactant to the first quaternary salt, so that the proper intermediate will be formed. This intermediate is treated either before or after purification with the second quaternary salt to form the asymmetric cyanine dye. If desired, the counterion Ψ can be exchanged at this point. One can react either of the heteroaromatic precursor salts with the carbon-providing reagent to form the required intermediate, or form the intermediate from the more readily available 2-methylazobenzazolum or 2-methylpolyazabenzazolum salts similar to the method described by Brooker et al but modified by use of an azabenzazolum or polyazabenzazolum salt.

Synthesis of the pentamethine dyes ($n = 2$) raises the same synthetic concerns about controlling the formation of an asymmetric intermediate. The three-carbon fragment that is required for the additional atoms in the methine moiety comes from a suitable precursor to malonaldehyde such as malonaldehyde dianil, 1,1,3,3-tetramethoxypropane, 1,1,3-trimethoxypropane, 3-(N-methylanilino)propenal or other reagents. The condensing agent for this reaction is usually 1-anilino-3-phenylimino-1-propene (US Patent No. 2,269,234 to Sprague, 1942), which generates the 2-(2-anilino-3-phenyl-1-propenyl)-3-methylbenzazolum tosylate intermediate.

The introduction of desired methine substituents (R^{30} , R^{31} , and/or R^{32}) is typically accomplished by modification of either the azabenzazolum moiety or the quinolinium/pyridinium moiety prior to condensation of the desired dye (Examples 28-31). Typically R^{32} is introduced by incorporation into the azabenzazolum moiety (Example 29), while R^{30} is introduced on the quinolinium/pyridinium moiety (Example 28). R^{31} may be introduced on either heterocyclic ring system, depending on the simplicity and accessibility of the resulting synthesis.

Those dyes having a quinoline or pyridine ring rather than a quinolinium or pyridinium are typically prepared by either heating a azabenzazolum or polyazabenzazolum salt that contains a good leaving group (chloride, methylthio, etc.) at the 2-position, with a 2- or 4-methyl substituted or unsubstituted quinoline or pyridine in the presence of acetic anhydride as an activator.

Alternatively, a corresponding N-methylquinolinium cyanine dye is dealkylated (typically demethylated) using a good nucleophile, such as an alkali metal salt of a thiol (e.g. sodium thiophenoxide) in a polar solvent (e.g. DMF, DMSO). Where R^2 is ethyl (or a higher alkyl), the N-methyl substituent on the pyridinium or quinolinium ring is removed selectively during dealkylation. Where the R^2 substituent is also methyl, two demethylated products may result, but the two products are readily separated by column chromatography. Where the N-substituent is a substituted alkyl, such as 2-methoxyethoxymethyl, other reagents, such as a strong acid, are used to generate the corresponding pyridine or quinoline end product.

TAIL

As described earlier, TAIL is composed of three parts: LINK, SPACER and CAP. The chemical composition of SPACER is determined by the chemistry required to attach the heteroatom in CAP with the dye core structure via LINK.

As described above, those dyes of the present invention that are 4-substituted heterocycles wherein R⁴ is a TAIL are most conveniently synthesized from the 2-halo substituted precursor either before or after condensation with the azabenzazolum or polkyazabenzazolum portion of the dye by a nucleophilic displacement reaction of the halogen by a thiol, alkoxide, or a primary or secondary amine.

CAP may be incorporated directly into TAIL before or after condensation of the second heterocyclic ring with the azabenzazolum or polyazabenzazolum salt, or CAP may be added or further modified at a later stage in the synthesis. For instance, when CAP is a cyclic or non-cyclic primary, secondary or tertiary amine, CAP can be alkylated to a quaternary ammonium (Examples 10, 11). This reaction can be used to increase the polarity of the dye and to thus restrict its penetration through the membrane of living cells, and to additionally increase the dye's affinity for nucleic acids.

Precursors to TAIL include, among other functional groups, carboxylic acids, halides, alcohols and thiols. Each of these reactive groups can be used to attach a heteroatom-containing moiety (i.e., CAP) to the dye's core structure, generally through the formation of amides, ethers or thioethers, which are incorporated into SPACER before or after attachment of SPACER to the dye's core structure.

Homo- and Heterodimer dyes

The dimeric dyes of the invention that are homodimers are typically prepared by condensation of two equivalents of a chemically reactive cyanine dye with one equivalent of a BRIDGE precursor, by methods known in the art (Example 12, 13). Heterodimeric dyes are prepared similarly, but the synthesis typically requires multiple steps in order to achieve the desired final product (as described in U.S. Patent No. 5,321,130; U.S. Patent No. 5,436,134; U.S. Patent No. 5,658,751; U.S. Patent No. 5,869,689; U.S. Patent No. 5,582,977; U.S. Patent No. 5,401,847; U.S. Patent No. 5,565,554; and U.S. 5,760,201).

Synthesis of Chemically Reactive Dyes and their Conjugates

As described for TAIL moieties above, -L-R_x moieties are typically prepared from 2-halo substituted heterocyclic precursors, either before or after condensation with the azabenzazolum or polyazabenzazolum portion of the dye by a nucleophilic displacement reaction of the halogen by a

thiol, alkoxide, or a primary or secondary amine, which is then incorporated into the covalent linkage L.

Prior to use in preparation of conjugates, chemically reactive forms of the dyes of the invention are typically dissolved in water or a water-miscible such as a lower alcohol, dimethylformamide (DMF), dimethylsulfoxide (DMSO), acetone, acetonitrile, tetrahydrofuran (THF), dioxane or acetonitrile. These dyes are typically combined with the sample under conditions of concentration, stoichiometry, pH, temperature and other factors that affect chemical reactions that are determined by both the reactive functional groups on the dye and the expected site of modification on the molecule to be modified. These factors are generally well known in the art of forming bioconjugates (Haugland, MOLECULAR PROBES, INC. HANDBOOK OF FLUORESCENT PROBES AND RESEARCH CHEMICALS, 1996; Haugland et al. "Coupling of Antibodies with Biotin" THE PROTEIN PROTOCOLS HANDBOOK, J.M. Walker, ed., Humana Press, (1996); Haugland "Coupling of Monoclonal Antibodies with Fluorophores" METHODS IN MOLECULAR BIOLOGY, VOL. 45: MONOCLONAL ANTIBODY PROTOCOLS, W.C. Davis, Ed. (1995)).

15

The examples below are given so as to illustrate the practice of this invention. They are not intended to limit or define the entire scope of this invention.

EXAMPLES

20

Example 1. Preparation of aza-benzoxazole precursors:

The following 4-methyl-2-methylthioxazolopyridinium tosylates are prepared by heating the corresponding 2-methylthioxazolopyridines (M.Y. Chu-Moyer and R. Berger, J. Org. Chem. 60, 5721-5725 (1995)) with one equivalent of methyl tosylate at 100-110 °C for one hour:

25

Compound 1

(4-methyl-2-methylthioxazolo[4,5-b]pyridinium tosylate)

30

Compound 2

(6-methyl-2-methylthioxazolo[5,4-c]pyridinium tosylate):

Compound 3

(1-methyl-2-methylthioxazolo[5,4-b]pyridinium tosylate):

Compound 4

(4-methyl-2-methylthioxazolo[4,5-b]quinolinium tosylate):

Example 2. Preparation of 5-methyl-2-methylthiothiazolo[4,5-b]pyridinium tosylate (Compound 5):

To 0.626 g of 2-methylthiothiazolo[4,5-b]pyridine (Smith, K., Lindsay, C., Morris, I. K., Matthews, I. and Pritchard, G.J., Sulfur Letters 17, 197-216 (1994)), is added 0.71 g methyl tosylate. The mixture is heated at 120 °C for one hour. After cooling, the resulting oily mixture is washed with 10 mL of ethyl acetate. After the ethyl acetate is decanted, Compound 5 is isolated as an oil.

Example 3. Preparation of 5-methyl-2-methylthiothiazolo[5,4-c]pyridinium tosylate (Compound 6):

Compound 6

A mixture of 0.127 g of 2-methylthiothiazolo[5,4-c]pyridine (from methylation of thiazolo[5,4-c]pyridine-2(1H)-thione with potassium carbonate and methyl iodide) and 0.143 g methyl tosylate is heated at 120 °C for one hour. Ethyl acetate (8 mL) is added, the mixture is stirred for 30 minutes, and Compound 6 is isolated by suction filtration.

Example 4. Preparation of 3-methyl-2-methylthiothiazolo[5,4-b]pyridinium tosylate (Compound 7):

Compound 7

- 5 A mixture of 1.285 g of 3-amino-2-chloropyridine, 0.48 g NaH (from a hexane-washed 60 % dispersion of NaH in mineral oil), 0.6 mL CS₂ and 10 mL DMF is heated at 110-120 °C for one hour to yield thiazolo[5,4-b]pyridine-2(1H)-thione. The thione is methylated with potassium carbonate and methyl iodide in DMF at room temperature to give the methylthio derivative, 2-methylthiothiazolo[5,4-b]pyridine, which is subsequently heated with one equivalent of methyl
10 tosylate at 100 °C for one hour to yield Compound 7.

Similarly, 6-chloro-4-methyl-2-methylthiothiazolo[4,5-b]pyridinium tosylate is prepared from 6-chlorothiazolo[4,5-b]pyridine-2(1H)-thione:

Compound 8

15

6-bromo-4-methyl-2-methylthiothiazolo[4,5-b]pyridinium tosylate is prepared from 2-amino-3,5-dibromopyridine:

Compound 9

- 20 4-methyl-2-methylthio-6-trifluoromethylthiazolo[4,5-b]pyridinium tosylate is prepared from 2-amino-3-chloro-5-trifluoromethylpyridine:

Compound 10

and 1-methyl-2,7-bis(methylthio)thiazolo[5,4-d]pyridinium tosylate is prepared from 5-amino-4,6-dichloropyrimidine:

Compound 11

- 5 **Example 5. Preparation of 3-acetoxy-1-methyl-2-acetylmino-1,2-dihydropyridine, *p*-toluenesulfonic acid salt (Compound 12):**

- 10 2-Amino-3-hydroxypyridine (14.48 g) is triacetylated by heating with 3 equivalents of acetic anhydride at 120-130 °C for 4 hours to yield, after silica gel column purification, 10.3 g of 3-acetoxy-2-acetimidopyridine. This intermediate compound is heated for 2 days at 65 °C with 3 equivalents of methyl tosylate to yield 7 g of Compound 12.

- 15 **Example 6. Preparation of 5-bromo-3-mercapto-2-methylaminopyridine (Compound 13):**

- 20 Compound 13 is prepared by heating Compound 9 (1.99 g) with 30 mL methanol and 15 mL of 10 % NaOH at 80 °C for 8 hours. The pH is adjusted to 6-7 with acetic acid and the volume is reduced to ~10 mL. The residue is filtered to yield 0.76 g of Compound 13.

Example 7. Preparation of Compound 14:

Compound 14

To 0.55 g of Compound 1 and 0.49 g of 1,4-dimethylquinolinium tosylate in 10 mL of CH₂Cl₂ at room temperature is added 0.24 mL of triethylamine. After 6 hours, the product is suction filtered to yield 0.42 g of Compound 14.

Example 8. Preparation of Compounds 15, 16, 17, 18, 19, 20, 21, and 44:

Compound 15

10

To a solution of 0.235 g of 4-methyl-1-phenyl-2-quinolone in 15 mL THF at -78 °C, is added 0.6 mL of a 2.5 M solution of 1-butyl lithium in THF. After 1 hr at -78 °C, 1 mL of acetic acid is added. The reaction mixture is stirred for 1 hr at room temperature. The volatiles are evaporated and the residue is dissolved in 10 mL CH₂Cl₂. Compound 1 (0.7 g) and 1 mL triethylamine are added. After 1 hr at room temperature the solvent is evaporated, the crude product is dissolved in 10 mL of methanol and the solution is then added to 2.5g NaI in 60 mL water. The product, Compound 15, is filtered and further purified by column chromatography on silica gel.

15

Similarly prepared except using phenyl lithium instead of butyl lithium is Compound 16, which can be recrystallized from a mixture of DMF and ethyl acetate.

20

Compound 16

Compound 17 is prepared similarly from 4-methyl-1-phenyl-2-quinolone

5

Compound 17

Compound 18 is prepared similarly from 1-ethyl-6,7-methylenedioxy-4-methyl-2-quinolone

Compound 18

10

Compound 19 is prepared similarly from 6-methoxy-1,4-dimethyl-2-quinolone

Compound 19

Compound 20 is prepared similarly from 6,7-dimethoxy-1,4-dimethyl-2-quinolone

Compound 20

5 Compound 21 is prepared similarly from 7-methoxy-1,4-dimethyl-2-quinolone.

Compound 21

Compound 44 is prepared similarly, except that Compound 9 is used instead of Compound 1:

10

Compound 44

Example 9. Preparation of Compound 22:

Compound 22

To 0.605 g of 4'-bromobenzyl-diethylamine in 10 mL of THF at -78°C under nitrogen is added 0.8 mL of a 2.5 M butyl lithium in THF, followed by a solution of 0.173 g of 1,4-dimethyl-2-quinolone in 10 mL of THF. After one hour at -78°C , 1 mL of acetic acid is added. After warming to room temperature for another hour the volatiles are evaporated and the residue is dissolved in 10 mL CH_2Cl_2 . To this solution is added 0.67 g of Compound 2, followed by 1 mL triethylamine. After one hour at room temperature the volatiles are evaporated and the residue is dissolved in 7 mL of methanol. This solution is added to a solution of 2.25 g NaI and 0.8 g NaOH in 50 mL water. Compound 22 is filtered, dried and recrystallized from a mixture of DMF and ethyl acetate.

Compound 23 is prepared similarly, using 6-methoxy-1,4-dimethyl-2-quinolone.

Compound 23

15

Example 10. Preparation of Compound 24:

Compound 24

The compound is prepared by heating 0.1 g of Compound 22 in 5 mL DMF with 0.5 mL methyl iodide at 60 °C in a sealed tube for 2 hours. After the reaction mixture is cooled to room temperature, 5 mL ethyl acetate is added and Compound 24 is collected by suction filtration.

Compound 25 is similarly obtained from Compound 23.

Compound 25

10

Example 11. Preparation of Compounds 26 and 27:

Compound 26

Compound 27

- 5 A mixture of 1.06 g of Compound 1, 0.88 g of 1-(3'-iodopropyl)-4-methylquinolinium iodide (U.S. Patent No. 5,321,130 to Yue et al. (1994)), 15 mL CH₂Cl₂ and 0.28 mL triethylamine is stirred at room temperature for 30 minutes. The volatiles are evaporated and the residue is dissolved in 10 mL methanol. The resulting solution is added to 4.5 g NaI in 60 mL water. Compound 26 is obtained by suction filtration. A solution of Compound 26 (0.15 g) and 1 mL of a 25%
10 trimethylamine in methanol solution are heated in a sealed tube at 75-80 °C for 7 hours. Following cooling and filtration, Compound 27 is recrystallized from a mixture of DMF and CH₂Cl₂.

Compound 47 is similarly prepared from Compound 9

Compound 47

Example 12. Preparation of Compound 28:

- A mixture of 0.2 g of Compound 26, 1.5 mL DMF and 0.029 mL N,N,N',N'-tetramethylpropanediamine is heated at 80 °C for 4 days. To the solution is added 6 mL of chloroform and Compound 28 is isolated by suction filtration.

**Compound 28**

10 **Example 13. Preparation of Compounds 45 and 46:**

**Compound 45**

Compound 46

A mixture of 2.1 g of Compound 9, 1.5 g of 1-(3'-iodopropyl)-4-methylquinolinium iodide, 0.7 mL triethylamine and 30 mL CH_2Cl_2 is stirred at room temperature for 2 hours. Following evaporation, the residue is dissolved in 30 mL DMF and added to 8 g NaI in 200 mL water. Compound 45 is obtained by suction filtration. Compound 45 (1 g), 0.125 mL of N,N,N',N'-tetramethylpropanediamine and 8 mL DMF are heated at 80 °C for 4 days. Following cooling, 24 mL of chloroform is added and Compound 46 is purified by recrystallization for a mixture of DMF and methanol.

10

Example 14. Preparation of Compounds 29, 30, and 41:

Compound 29

Compound 30

A mixture of 6 g of Compound 1, 3 g of 4-methyl-1-phenyl-2-quinolone, 8.9 mL diisopropylethylamine, and 1.2 mL of trimethylsilyl trifluoromethanesulfonate is heated at reflux in 100 mL of CH_2Cl_2 for 1 hour. The reaction mixture is cooled on ice and 100 mL of water is added slowly with stirring. The layers are separated and the aqueous layer is extracted with chloroform. The combined organic layers are washed with brine and dried over Na_2SO_4 . The crude 4-oxazolopyridinylmethylidenequinolone thus obtained is heated at reflux for 3 hours with 5.8 mL of phosphorus oxychloride and 100 mL of dichloroethane. The reaction mixture is cooled to room temperature, 100 mL of water is added and after 30 min, the crude product is recovered by filtration. The crude product is purified by chromatography on a silica gel column to yield Compound 29. A mixture of 0.1 g of Compound 29, 10 mL of dichloroethane and 0.27 mL of diethylamine is heated at 60 °C in a sealed tube for 2.5 hours. The volatile components are evaporated and the crude residue is purified by chromatography on a silica gel column to yield Compound 30.

Preparation of Compound 41 is similar to that of Compound 29, except that Compound 9 is used instead of Compound 1.

Compound 41

Example 15. Preparation of Compound 31:

Compound 31

Triethylamine (0.1 mL) is added to 0.176 g of Compound II and 0.165 g of 1,4-dimethylquinolinium tosylate in 10 mL of CH₂Cl₂ at room temperature. After stirring for one hour, the organic layer is evaporated and the residue is dissolved in 2 mL of methanol and added dropwise to a solution of 1.5 g NaI in 25 mL of water. Compound 31 is recovered by suction filtration.

Example 16. Preparation of Compound 32:

Compound 32

A mixture of 0.35 g of 1,4-dimethyl-2-quinolone, 0.56 mL phosphorus oxychloride, and 0.05 mL DMF is heated in 10 mL toluene at 70 °C for 2 hours. After cooling, 20 mL CH₂Cl₂ and 1.11 g 2-mercaptopyridine are added and the reaction mixture is heated overnight at 40 °C. The volatiles are evaporated and to the residue is added 0.84 g of Compound 1, 1.4 mL of triethylamine and 20 mL CH₂Cl₂. After 2 hours, the volatiles are evaporated, the residue is dissolved in 3 mL methanol and the solution is added to 4.5 g NaI in 20 mL water. Compound 32 is purified by recrystallization from a mixture of DMF and ethyl acetate.

Example 17. Preparation of Compound 33:

Compound 33

A mixture of 0.244 g of Compound 7, 0.225 g of 1,4-dimethylquinolinium tosylate, 0.14 mL triethylamine and 10 mL CH_2Cl_2 is stirred at room temperature overnight. The volatiles are
 5 evaporated, residue is dissolved in 4 mL of methanol, and the resulting solution is added to 1.5 g NaI in 25 mL water. Compound 33 is obtained by suction filtration.

10

Compounds 34, 35, 36, 37, 38, 39, and 40 are similarly prepared from 1,4-dimethylquinolinium tosylate and Compounds 6, 11, 4, 10, 5, 9, and 8 respectively.

Compound 34

Compound 35

Compound 36

15

Compound 37

Compound 38

5

Compound 39

Compound 40

10 Example 18. Preparation of Compound 42:

Compound 42

A mixture of 0.2 g of Compound 8, 0.065 mL of lepidine, 0.28 mL acetic anhydride and 5 mL DMF is heated at 110-120 °C for one hour. The reaction mixture is carefully diluted with a mixture of sodium bicarbonate and water and then extracted with chloroform. The chloroform is evaporated, and the resulting residue is purified by silica gel chromatography to yield Compound 42.

Compound 43 is similarly prepared from Compound 1.

Compound 43

10

Example 19. Preparation of Compound 48:

Compound 48

Compound 1 (0.36 g), 0.28 g of 1,4-dimethylpyridinium tosylate, 0.17 mL of triethylamine and 20 mL of CH₂Cl₂ are stirred at room temperature for one hour, then stirred for an additional 3 days at -20 °C. Compound 48 is isolated by suction filtration.

Example 20. Preparation of Compound 49:

Compound 49

20

A solution of 4.2 mg of 3-methyl-2-methylthio-4,5,7-trifluorothiazolo[5,4-c]pyridinium tosylate (from 4-amino-2,3,5,6-tetrafluoropyridine by a procedure similar to that used for preparation of Compound 8), 3.3 g of 1,4-dimethylquinolinium tosylate and 1.7 mL of triethylamine is stirred in 20 mL CH₂Cl₂ at room temperature for 1 hour. The volatiles are evaporated and the residue is purified by chromatography on a silica gel column. The product is converted to Compound 49 with NaI in water.

Example 21. Preparation of Compound 50:

Compound 50

A mixture of 0.33 g of 1,4-dimethylquinolinium tosylate, 0.24 g of N,N'-diphenylformamidine, and 0.3 mL acetic anhydride is heated at 130 °C for 2 hours. Ethyl acetate (20 mL) is added and the solution is heated at reflux for 20 minutes. The mixture is cooled, and the resulting solid is dissolved in 5 mL dichloroethane. Compound 12 (0.34 g), 0.35 mL of diisopropylethylamine and 0.2 mL acetic anhydride are added. After stirring for 3 hours at room temperature, the volatiles are evaporated, the residue is dissolved in 3 mL of methanol and the solution is added dropwise to 1.5 g NaI in 20 mL water. Compound 50 is recovered by filtration and purified by chromatography on a silica gel column.

Example 22. Preparation of Compound 51:

Compound 51

A mixture of 1.9 g of Compound 12, 1.18 g of N,N'-diphenylformamidine, 2.1 mL of triethylamine and 50 mL dichloroethane is heated at 60-65 °C for 2 hours. After cooling, one equivalent of 1,4-dimethyl-2-phenylquinolinium salt (prepared in a manner similar to that for Compound 16) in 10 mL of dichloroethane is added, followed by 0.7 mL of additional triethylamine and 1.41 mL of acetic anhydride. After three hours, the volatiles are evaporated, the residue is dissolved in 10 mL DMF and the solution is added to 7.5 g of NaI in 120 mL water. Compound 51 is recrystallized from a mixture of methanol and ethyl acetate.

10 Example 23. Preparation of Compound 52:

Compound 52

A mixture of 0.18 g of Compound 2, 0.17 g 1,4-dimethylpyridinium tosylate, 0.09 mL triethylamine and 20 mL CH_2Cl_2 is stirred at room temperature overnight. The volatiles are evaporated, the residue is dissolved in 2 mL of MeOH and added to 1.5 g NaI in 12 mL water. The aqueous layer is extracted with 1-butanol and Compound 52 is purified by chromatography on a silica gel column.

Example 24. Preparation of Compound 53:

20

Compound 53

Compound 1 (0.35 g), 0.33 g of 1,2-dimethylquinolinium tosylate, 0.15 mL of triethylamine and 20 mL CH_2Cl_2 are stirred at room temperature for one hour. The reaction is suction filtered to yield Compound 53, which is purified by chromatography on silica gel.

Example 25. Preparation of Compound 54:

Compound 54

A mixture of 0.173 g of 1,4-dimethyl-2-quinolone, 0.28 mL phosphorus oxychloride, 0.025 mL DMF and 5 mL toluene is heated at 70 °C for 6 hours. Following cooling, 10 mL of methanol is added and the solution is heated at 45 °C for two hours. The volatiles are evaporated, 0.352 g of Compound 1, 0.7 mL of triethylamine and 20 mL of CH₂Cl₂ are added and the mixture is stirred overnight at room temperature. The solvent is evaporated, the crude product is dissolved in 3 mL methanol and added to 2.5 g of sodium perchlorate in 20 mL water. Compound 54 is collected by filtration, dried, and recrystallized from a mixture of DMF and ethyl acetate.

10

Example 26. Preparation of Compound 55:

Compound 55

Compound 13 (55 mg) is stirred with 10 mg sodium borohydride for 1.5 hours. Acetic acid (0.6 mL) is added to quench the reaction. The volatiles are evaporated. The crude product is stirred with 0.21 mL triethylamine, 0.19 mL acetic anhydride and ~10 mL CH₂Cl₂. After one hour at room temperature and 30 minutes at 50-60 °C, the volatiles are evaporated. Ethyl acetate (10 mL) is added, followed by 5 mL of hexanes. The solid is filtered and the salt thus obtained is stirred overnight at room temperature with a mixture of 65 mg N,N'-diphenylformamidine and 0.1 mL triethylamine in 4 mL dichloroethane. To this is added 150 mg of 1,4-dimethyl-2-phenylquinolinium derivative in 10 mL of acetonitrile, another 0.1 mL of triethylamine and 0.07 mL acetic anhydride. After 1.5 hr at room temperature the volatiles are evaporated, the residue is dissolved in 3 mL methanol and the solution is added to 1 g NaI in 20 mL water. Compound 55 is isolated by suction filtration followed by purification on a silica gel column.

Example 27. Preparation of Compound 56:

Compound 56

5

A solution of 1.14 g of Compound 12 in 30 mL of dichloroethane and 1.7 mL triethylamine is stirred at room temperature for 30 minutes. To this is added 0.7 g of N,N'-diphenylformamidine and the mixture is heated at 65 °C for 4 hours. Following cooling, 0.84 g of 1-(4'-sulfobutyl)-4-methylquinolinium inner salt is added, followed by 0.6 mL of acetic anhydride. The mixture is

10

Example 28. Preparation of Compound 57

Compound 57

15

To 4-ethyl-1-methyl-2-quinolone in THF at -78 °C is added 1.5 equivalent of phenyllithium, and the resulting solution is kept cold and stirred for one hour. Four equivalents of acetic acid are introduced and the reaction mixture is allowed to stir at room temperature for 3 hours. All the volatile components are then removed under reduced pressure. The resulting residue is dissolved in

20

methylene chloride and one equivalent of Compound 1 (4-methyl-2-methylthioxazolo[4,5-b]pyridinium tosylate) is introduced followed by 5 equivalents of triethylamine. The resulting product is purified by column chromatography on silica gel.

Example 29. Preparation of Compound 58:

Compound 58

5

To 2,4-dimethyl-thiazolo-[4,5-b]pyridinium tosylate in pyridine at room temperature is added 1.2 equivalent of benzoyl chloride, and the resulting mixture is stirred at room temperature overnight. The resulting intermediate is isolated by silica gel column chromatography. This intermediate is then heated at reflux in 3 equivalents of phosphorous oxychloride for 3 hours. Excess phosphorous
10 oxychloride is removed under reduced pressure and the residue is stirred in methylene chloride with one equivalent of 1,4-dimethyl-quinolinium tosylate and 4 equivalents of triethylamine to obtain the desired product.

Example 30. Preparation of Compound 59:

15

Compound 59

To a mixture of one equivalent each of 1,4-dimethylquinolinium tosylate and malonaldehyde dianil hydrochloride in acetic acid, is added one equivalent of acetic anhydride and the resulting reaction
20 mixture is heated at 150 °C for 30 minutes. All volatile components are removed under reduced pressure and methylene chloride is introduced followed by the addition of one equivalent of 2-ethyl-4-methyloxazolo[4,5-b]pyridinium tosylate, 1.5 equivalent of acetic anhydride, and 3 equivalents of triethylamine to obtain the desired product.

25 Example 31. Preparation of Compound 60:

Compound 60

A mixture of 135 mg of 2-benzoylmethylidene-3-methyl-2,3-dihydrobenzothiazole and 230 mg of phosphorous oxychloride is heated at reflux in 5 mL of dichloroethane for 2 hours. Solvent and excess reagents are evaporated under reduced pressure and 30 mL of ethyl acetate is added. After stirring for 30 minutes at room temperature, the resulting solid is collected by filtration and resuspended in 15 mL of methylene chloride. To the mixture is added 165 mg of 1,4-dimethylquinolinium tosylate and 0.14 mL of triethylamine. After stirring at room temperature overnight, the desired product is recovered by recrystallization. When associated with DNA, Compound 60 exhibits excitation and emission wavelengths of 642 nm and 659 nm, respectively.

Example 32. Detecting double-stranded DNA in solution:

Samples containing 0.1 ng/mL to 1 microgram/mL double-stranded DNA are prepared in 10 mM Tris-HCl, 1 mM EDTA, pH 7.5. The selected dye of the invention is dissolved in DMSO at a concentration of 1–10 mM and then diluted into the same buffer at a concentration sufficient to achieve final optical densities of 0.1 and 0.01 at 500 nm, 530 nm, 540 nm or 560 nm. Equal volumes (100 microliters each) of DNA sample solution and dye solution at each concentration are combined and mixed gently at room temperature in a microplate well. Samples are allowed to equilibrate for 5–60 minutes, protected from light, and the fluorescence of the sample is measured using a fluorescence microplate reader. DNA concentration is determined by comparison of the sample fluorescence with a standard curve obtained with that dye for each dye concentration. The sensitivity limit of several dyes in this assay is shown (Table 5).

Table 5. Detecting double-stranded DNA in solution.

Dye	Sensitivity Limit (ng/ml)

Example 33. Detecting oligonucleotides in solution:

Selected dyes of the invention are dissolved in DMSO at 1-10 micromolar concentration, then diluted

into 10 mM Tris-HCl, 1 mM EDTA, pH 7.5 to a final optical density of 0.1 or 0.01 at 530 nm or 540 nm. The resulting dye solutions are combined with an equal volume of an 18-base oligodeoxynucleotide sequencing primer solution at concentrations of 0.1 ng/mL to 1 microgram/mL in the same buffer. The resulting mixture is mixed gently and incubated for 5–60 minutes at room temperature, protected from light, and the sample fluorescence is measured in a fluorescence microplate reader. Typical sensitivity limits for some dyes are shown in Table 6.

Table 6. Detection of oligonucleotides in solution.

Dye	Sensitivity Limit (ng/mL)	
	Low dye concentration (0.01 OD)	High dye concentration (0.1 OD)
<u>Excitation 530 nm/Emission 560 nm</u>

Example 34. Detecting RNA in solution:

Selected dyes of the invention are dissolved in DMSO at 1–10 micromolar concentration, then diluted into 10 mM Tris-HCl, 1 mM EDTA, pH 7.5 to a final optical density of 0.1 or 0.01 at 530 nm or 540 nm. These dye solutions are combined with an equal volume of *Escherichia coli* ribosomal RNA at concentrations ranging from 0.25 ng/mL to 1 microgram/mL in microplate wells. The resulting mixtures are mixed gently and incubated for 5–60 minutes at room temperature, protected from light, and the sample fluorescence is measured. Typical sensitivity limits for selected dyes are shown in Table 7.

Table 7. Detecting RNA in solution.

Dye	Sensitivity Limit (ng/mL)	
	Low dye concentration (0.01 OD)	High dye concentration (0.1 OD)

Compound 19	10	20
Compound 23	2.5	200
Compound 25	1.2	200

Example 35. Detecting double-stranded DNA in the presence of single-stranded DNA:

5

Selected dyes of the invention exhibit high sensitivity for detecting double-stranded DNA, but exhibit little sensitivity for detecting single-stranded nucleic acids, making them particularly useful for quantitating double-stranded DNA in the presence of single-stranded DNA, RNA or oligonucleotide primers (such as might be present in a PCR reaction). Samples containing nucleic acids at a concentration of 2 micrograms/mL are combined with Compound 16, Compound 22, or Compound 24 at a final dye concentration of 1 micromolar in 10 mM Tris-HCl, 1 mM EDTA, pH 7.5, and mixed gently. The resulting mixture is allowed to incubate for 5–60 minutes at room temperature, protected from light, and sample fluorescence is measured using a fluorescence microplate reader, with excitation at 540 nm and emission at 570 nm. Double-stranded DNA is detected preferentially (Figures 1 and 2). If, however, the dye concentration is reduced relative to the concentration of single-stranded nucleic acids, the fluorescence upon binding those nucleic acids increases relative to that of the double-stranded DNA-dye complex. Thus the assay is always performed in sufficient dye excess.

20 Example 36. Detecting nucleic acids in gels:

DNA samples are loaded onto agarose or polyacrylamide gels and electrophoresed using standard conditions. Selected dyes of the invention are dissolved in DMSO at a concentration of 1–10 micromolar and diluted into 0.5X TBE buffer to a final concentration of 1 micromolar dye. Gels are incubated for 20–90 minutes in this staining solution, with gentle agitation, at room temperature, protected from light. Nucleic acids are visualized by transillumination at 300 nm, followed by direct visual detection or photography using Polaroid black-and-white print film. Nucleic acids are

alternatively visualized by scanning using a FMBIO II laser scanner with a 532 nm frequency-doubled YAG laser source or a charge-coupled device camera system coupled with an ultraviolet (300 nm) light source, or a visible light transilluminator. The sensitivity of detection obtained using these dyes and various imaging instruments is shown in Table 8.

Table 8. Sensitivity for detecting double-stranded bacteriophage λ cI857 DNA that is digested with *Hind*III restriction endonuclease, and separated in agarose gels.

nd indicates that a value was not determined for this dye with this gel imager.

Example 37. Detecting nucleic acids arrayed on glass slides:

Nucleic acid arrays are prepared on glass slides, using an automated arraying robot. The slide
5 surface is optionally blocked with a solution of 0.1% Ficoll (Type 400, Amersham Pharmacia) and
0.1% polyvinylpyrrolidone. Arrays are allowed to dry and then overlaid with a solution containing 1
micromolar dye in 10 mM Tris-HCl, 1 mM EDTA, pH 7.5. Suitable dyes for this purpose include
Compound 15, Compound 16, Compound 22, Compound 23, Compound 24, and Compound 25.
Slides are incubated with the overlay solution for 5–60 minutes at room temperature, with light
10 protection, and then are washed briefly in the same buffer without the dye. The amount of nucleic
acid in each spot on the array can be measured by comparison of the fluorescence of an unknown
sample with that of standards of known concentration, which are applied to the same slide.
Fluorescence measurement is performed using a fluorescence microscope with a mercury or xenon
lamp, equipped with appropriate optical filters, a charge-coupled device and image analysis software,
15 or using a dedicated array reader with a 532 nm or 546 nm excitation source, such as the
GENEARRAY 2000 (General Scanning).

Example 38. Detecting proteins in solution:

Compound 51 and Compound 44 are dissolved in DMSO at 1–10 mM and then diluted into 10 mM
20 Tris-HCl, 1 mM EDTA, pH 7.5, containing 0.05% sodium dodecyl sulfate, to a final concentration of 2
micromolar. This dye solution is combined with samples containing bovine serum albumin at 100
ng/mL to 10 micrograms/mL. Samples are optionally incubated for 10 minutes at 90 °C and then
cooled to room temperature, or are incubated for 5–60 minutes at room temperature. Fluorescence is
25 measured using a fluorescence microplate reader with excitation at 540 nm and emission at 590 nm
for Compound 44 and with excitation at 600 nm and emission at 670 nm for Compound 51. The
fluorescence signal obtained from Compound 44 or 51 in buffer alone (control) is subtracted from the
fluorescence recorded for the protein-containing samples in order to determine the intensity of the
signal that is due to the presence of protein. Protein concentrations are then determined by
30 comparison of the signal intensity thus obtained with the signals obtained using a dilution series of
known concentration prepared using either the same protein or a protein standard, such as bovine
serum albumin. The sensitivity limit for either dye under either condition is about 100 ng/mL bovine
serum albumin (Figures 3 and 4).

35 Example 39. Detection of proteins in sodium dodecyl sulfate (SDS)-polyacrylamide gels:

The pure protein or mixture of proteins of interest is prepared in Loading Buffer (50 mM Tris-HCl,
pH 6.8, 2% SDS, 10% glycerol, and 0.015% bromophenol blue). Dithiothreitol is added to each

sample, to a final concentration of 0.1 M. The samples are heated for 4-5 minutes at 90-95 °C and loaded onto a 15% Tris-glycine polyacrylamide mini- or full-sized gel containing 0.05%-0.1% SDS, with a 4% stacking gel. The gel is electrophoresed under standard conditions, in a standard Tris-glycine buffer containing 0.05%-0.1% SDS. The resulting gel is transferred to a small staining dish containing a 1-3 µM solution of Compound 25 in 7.5% acetic acid (in water). The staining solution is then covered with foil to protect it from room light and gently agitated for 45 minutes-1 hour. After 10 minutes, the protein bands are readily apparent, but sensitivity improves over about 30-40 minutes. The gel is then removed from the staining dish, rinsed briefly in 7.5% acetic acid and transferred directly to a UV-transilluminator. The gel, with the stained protein bands is photographed using 300 nm transillumination and black and white POLAROID 667 print film with a Wratten 9 gelatin filter. The stained bands appear visually as brightly fluorescent orange bands. Proteins appear as white bands on a grey to black background in the POLAROID photograph.

Although Compound 25 is used in this procedure, a variety of other dyes of the invention are useful as electrophoretic gel stains, yielding stained gels that possess bands having fluorescence emission from yellow to red.

Example 40. Detection of apoptosis:

A 1 mM solution of Compound 27 in DMSO is prepared. Jurkat human T-cell leukemia cells are treated with 10 µM camptothecin to induce apoptosis. A sample of the cells (1×10^6 cells/mL) is incubated with enough of the Compound 27 stock solution to give a final dye concentration of 0.1 µM, and sufficient propidium iodide to give a final concentration of 1.5 µM. After incubating for 30 minutes on ice, the cell samples are analyzed on a FACS Vantage flow cytometer using 488-argon laser excitation, with emission at 530/30 and 675/20. Apoptotic cells are compared to control cells that were incubated with the same final concentration of DMSO used in the staining solution. A plot of FL1 versus FL3 shows that Compound 27 is capable of differentiating between apoptotic and normal cells. Late stage apoptotic and necrotic cells are stained with propidium iodide.

It is to be understood that, while the foregoing invention has been described in detail by way of illustration and example, numerous modifications, substitutions, and alterations are possible without departing from the spirit and scope of the invention as described in the following claims.

1. A compound of the formula

wherein A represents the atoms necessary to form one to two fused aromatic rings having 6 atoms in each ring, at least one of which is a nitrogen atom, said ring or rings being optionally further substituted one or more times by alkyl having from 1-6 carbons, alkoxy having from 1-6 carbons, trifluoromethyl, halogen, or -L-R_x; or -L-S_y;

X is O, S, Se, NR¹⁵, or CR¹⁶R¹⁷, where R¹⁵ is H or an alkyl group having 1-6 carbons; and R¹⁶ and R¹⁷, which may be the same or different, are independently alkyl groups having 1-6 carbons, or R¹⁶ and R¹⁷ taken in combination complete a five or six membered saturated ring;

α is 0 or 1;

R² is an alkyl group having 1-6 carbons that is optionally substituted by sulfonate, carboxy, or amino; or R² is -L-R_x or -L-S_x; or TAIL; or BRIDGE-DYE;

$$n = 0, 1 \text{ or } 2;$$

Y is $-\text{CR}^3=\text{CR}^4-$;

p and $m = 0$ or 1 , such that $p + m = 1$;

R³, R⁴, R⁶, and R⁷ are independently H; an alkyl that is saturated or unsaturated, linear or branched, having 1-6 carbons; or a halogen; or a CYCLIC SUBSTITUENT; or -OR⁸, -SR⁸, -(NR⁸R⁹); or TAIL; or BRIDGE-DYE; or -L-R_x; or -L-S_c; where R⁸ and R⁹, which can be the same or different, are independently alkyl groups having 1-6 carbons; or 1-2 alicyclic or aromatic rings; or R⁸ and R⁹ taken in combination are -(CH₂)₂-V-(CH₂)₂- where V is a single bond, -O-, -CH₂-, or -NR¹⁰-, where R¹⁰ is H or an alkyl having 1-6 carbons;

or R^6 and R^7 form a fused aromatic ring $-R^{11}=R^{12}-R^{13}=R^{14}-$ wherein R^{11} , R^{12} , R^{13} , and R^{14} are optionally and independently alkyl that are saturated or unsaturated, linear or branched, having 1-6 carbons; or $-OR^8$, $-SR^8$, or $-(NR^8R^9)$; or a CYCLIC SUBSTITUENT; or a TAIL; or BRIDGE-DYE; or

5 $-L-R_\alpha$; or $-L-S_c$;

R^5 is an alkyl that is saturated or unsaturated, linear or branched, having 1-6 carbons; or R^5 is a CYCLIC SUBSTITUENT; or R^5 is TAIL; or BRIDGE-DYE; or $-L-R_\alpha$; or $-L-S_c$; or R^5 is a pair of electrons;

10 R^{30} , R^{31} , and R^{32} are independently H, C_1-C_6 alkyl having 1-6 carbons, cycloalkyl having 3-10 carbons, aryl, or heteroaryl;

wherein

15 L and BRIDGE are independently a single covalent bond, or a covalent linkage that is linear or branched, cyclic or heterocyclic, saturated or unsaturated, having 1-16 nonhydrogen atoms selected from the group consisting of C, N, P, O and S, such that the linkage contains any combination of ether, thioether, amine, ester, amide bonds; or single, double, triple or aromatic carbon-carbon

20 bonds; or phosphorus-oxygen, phosphorus-sulfur bonds, nitrogen-nitrogen or nitrogen-oxygen bonds; or aromatic or heteroaromatic bonds;

R_α is a reactive group;

25 S_c is a conjugated substance;

TAIL is a heteroatom-containing moiety;

DYE is a compound of the formula

wherein A, X, R², α, n, Y_m, Y_p, R³, R⁴, R⁵, R⁶, R⁷, R⁸, R⁹, R¹⁰, R¹¹, R¹², R¹³, R¹⁴, R¹⁵, R¹⁶, R¹⁷, R¹⁸, R¹⁹, R²⁰, R²¹, R²², R²³, R²⁴, R³⁰, R³¹, R³², TAIL, CYCLIC SUBSTITUENT are as defined above;

5 that is bound to BRIDGE at one of R³, R⁴, R⁵, R⁶, or R⁷.

2. A compound, as claimed in Claim 1, having the formula

10

the formula

15 the formula

the formula

20

or the formula

5

wherein either α or β is 1.

3. A compound, as claimed in Claim 1, wherein TAIL is a heteroatom-containing moiety having the
10 formula LINK-SPACER-CAP;

wherein

15 LINK is a single covalent bond, -O-, -S-, or -NR²⁰-; where R²⁰ is H, a linear or branched alkyl having 1-8 carbons, or R²⁰ is -SPACER'-CAP;

20 SPACER and SPACER', which may be the same or different, are covalent linkages, linear or branched, cyclic or heterocyclic, saturated or unsaturated, each having 1-16 nonhydrogen atoms selected from the group consisting of C, N, P, O and S, such that the linkage contains any combination of ether, thioether, amine, ester, amide bonds; or single, double, triple or aromatic carbon-carbon bonds; or phosphorus-oxygen, phosphorus-sulfur bonds, nitrogen-nitrogen or nitrogen-oxygen bonds; or aromatic or heteroaromatic bonds;

25 CAP and CAP', which may be the same or different, are -O-R²¹, -S-R²¹, -NR²¹R²², or -N-R²¹R²²R²³Ψ-;

wherein

R^{21} , R^{22} , and R^{23} are independently H, or a linear or branched alkyl or cycloalkyl having 1-8 carbons, optionally further substituted by hydroxy, alkoxy having 1-8 carbons, carboxyalkyl having 1-8 carbons, or phenyl, where phenyl is optionally further substituted by halogen, hydroxy, alkoxy having 1-8 carbons, aminoalkyl having 1-8 carbons, or carboxyalkyl having 1-8 carbons; or, one or
 5 more of R^{21} , R^{22} and R^{23} , taken in combination with SPACER or SPACER' or R^{20} forms a 5- or 6-membered aromatic, heteroaromatic, alicyclic or heteroalicyclic ring, the heteroatoms selected from O, N or S; where Ψ^- is a compatible counterion;

or

10

CAP and CAP' are independently

and Ψ^- are as defined previously.

15

4. A compound, as claimed in Claim 1, wherein each R^2 is independently ethyl or methyl, each X is independently O or S, each n is independently 0 or 1, and R^{30} , R^{31} , and R^{32} are each H.

5. A compound, as claimed in Claim 1, wherein at least one R^3 , R^4 , R^5 , R^6 , R^7 , R^{11} , R^{12} , R^{13} , and R^{14} is
 20 a CYCLIC SUBSTITUENT that is a substituted or unsubstituted naphthyl, phenyl, thienyl, or cycloalkyl having 3-8 carbons.

6. A compound, as claimed in Claim 1, wherein CAP and CAP', which may be the same or different, are $-NR^{21}R^{22}$, or $-N^+R^{21}R^{22}R^{23}\Psi^-$, wherein R^{21} , R^{22} , and R^{23} are independently H, or a linear or
 25 branched alkyl or cycloalkyl having 1-8 carbons; R^{20} is H or a linear or branched alkyl having 1-8 carbons; and SPACER and SPACER' are independently linear alkylenes having 1-8 carbons; or incorporate a phenylene ring.

7. A compound, as claimed in Claim 1, wherein R^4 is a TAIL or BRIDGE-DYE.

30

8. A compound, as claimed in Claim 1, wherein R^5 is a TAIL; or a CYCLIC SUBSTITUENT; or BRIDGE-DYE.

9. A compound, as claimed in Claim 8, wherein R⁵ is a TAIL or a BRIDGE-DYE, and TAIL and BRIDGE incorporate at least one quaternary nitrogen atom.

5 10. A compound, as claimed in Claim 1, wherein each R³, R¹¹, R¹², R¹³ and R¹⁴ is hydrogen.

11. A compound, as claimed in Claim 1, wherein

R⁵ is a linear or branched alkyl having 1-6 carbons; and

10

R⁴ is halogen, a CYCLIC SUBSTITUENT, -OR⁸, -SR⁸, -(NR⁹R⁹), TAIL, BRIDGE-DYE, -L-R_a, or -L-S_c.

12. A compound, as claimed in Claim 1, wherein S_c is an amino acid, a peptide, a protein, a polysaccharide, a nucleotide, an oligonucleotide, a nucleic acid, a lipid, a polymeric microparticle, a
15 biological cell, or a virus.

13. A compound, as claimed in Claim 1, wherein S_c is an oligonucleotide, a nucleic acid, or a DNA-binding protein.

20 14. A compound, as claimed in Claim 2, wherein

each X is O;

each n is independently = 0, 1, or 2;

25

each m = 1;

each R³⁰, R³¹, and R³² are H; and

30 R⁵ is a linear or branched alkyl having 1-6 carbons, a TAIL, a CYCLIC SUBSTITUENT, or BRIDGE-DYE.

15. A fluorescent complex comprising a nucleic acid polymer non-covalently associated with one or more compounds as defined in claims 1-14.

35

16. A fluorescent complex, as claimed in Claim 15, wherein the nucleic acid polymer is a chromosome, or a natural or synthetic oligonucleotide.

17. A fluorescent complex, as claimed in Claim 15, wherein said complex is present in an electrophoretic matrix, in a flowing medium, is enclosed in a biological structure, or is present in an aqueous or aqueous miscible solution.

5 18. A fluorescent complex, as claimed in Claim 15, wherein said nucleic acid is obtained from a biological fluid.

19. A fluorescent complex, as claimed in Claim 15, said complex is enclosed in a biological structure that is a cell.

10

20. A fluorescent complex, as claimed in Claim 19, wherein said cell is undergoing apoptosis, necrosis, or is in a cycle of growth or cell division.

21. A composition comprising:

15

a) one or more compounds as defined in claims 1-14;

b) a detergent; and

20

c) a poly(amino acid),

in a cell-free aqueous solution where said detergent is present at a concentration less than the critical micelle concentration for that detergent.

25 22. A composition, as claimed in Claim 21, where said detergent is an alkyl sulfate or alkyl sulfonate salt.

23. A composition, as claimed in Claim 21, wherein said poly(amino acids) are present on or in a solid or semi-solid matrix.

30

24. A composition, as claimed in Claim 23, wherein said matrix is a membrane or an electrophoretic gel.

25. A method of staining poly(amino acids), comprising the steps of:

35

a) combining a sample that contains or is thought to contain a poly(amino acid) with a staining mixture that contains one or more compounds as defined in claims 1-14;

b) incubating the combined mixture for a time sufficient for the compound in the staining mixture to associate with the poly(amino acid) in the sample mixture to form a compound-poly(amino acid) complex that gives a detectable optical response upon illumination;

5 d) illuminating said compound-poly(amino acid) complex; and

e) observing said detectable optical response.

10 26. A method, as claimed in Claim 25, further comprising heating the sample mixture prior to combining with the staining mixture, or heating the combined mixture.

27. A method, as claimed in Claim 25, further comprising removing, destroying, or dispersing below the critical micelle concentration any biological membranes that are present in the sample mixture.

15 28. A method, as claimed in Claim 25, further comprising adding an anionic detergent to the sample mixture, staining mixture or combined mixture.

29. A method, as claimed in Claim 28, wherein said detergent is an alkyl sulfate or alkyl sulfonate salt having 6-18 carbons; that is present in a concentration of less than 0.1% by weight.

20 30. A method, as claimed in Claim 25, wherein said detectable optical response is a fluorescence response.

25 31. A method, as claimed in Claim 25, further comprising quantitating said poly(amino acid) by measuring said detectable optical response and comparing said measurement with a standard.

32. A method, as claimed in Claim 25, further comprising electrophoretically separating the sample mixture before, after, or while it is combined with the staining mixture.

30 33. A method, as claimed in Claim 25, further comprising transferring the sample mixture to a solid or semi-solid matrix before or after combining with the staining mixture.

34. A method, as claimed in Claim 25, further comprising adding an additional reagent to the sample mixture, the staining mixture, or the combined mixture.

35 35. A method of staining nucleic acids, comprising

a) combining a sample that contains or is thought to contain a nucleic acid with a mixture

containing a compound as defined in claims 1-14;

- b) incubating the sample and mixture for a time sufficient for the compound to combine with the nucleic acid in the sample to form one or more compound-nucleic acid complexes that give a
5 detectable fluorescent signal.

36. A method of staining nucleic acids, as claimed in Claim 35, wherein said sample or said mixture comprises an electrophoretic gel, a biological fluid, cells, or cell-free nucleic acids.

- 10 37. A kit, comprising:

a) a compound as defined in claims 1-14, wherein said compound is present as a stock solution.

38. A kit, as claimed in Claim 37, further comprising one or more of the following:

15

a) a buffer suitable for dilution of the stock solution;

b) a fluorescence standard;

20

c) a nucleic acid;

d) a poly(amino acid);

e) an additional detection reagent;

25

f) a silicon chip; or

g) a glass slide.

- 30 39. A kit, as claimed in Claim 38, wherein the additional detection reagent is an organelle stain, an immunoreagent, a drug, an enzyme, or an enzyme substrate.

Publication Title:

AZA-BENZAZOLIUM CONTAINING CYANINE DYES

Abstract:

Unsymmetrical cyanine dyes that incorporate an aza-benzazolum ring moiety are described, including cyanine dyes substituted by a cationic side chain, monomeric and dimeric cyanine dyes, chemically reactive cyanine dyes, and conjugates of cyanine dyes. The subject dyes are virtually non-fluorescent when diluted in aqueous solution, but exhibit bright fluorescence when associated with nucleic acid polymers such as DNA or RNA, or when associated with detergent-complexed proteins. A variety of applications are described for detection and quantitation of nucleic acids and detergent-complexed proteins in a variety of samples, including solutions, electrophoretic gels, cells, and microorganisms.
